[a] EUA request (Interim analysis) November 11 2020
*Safety Analyses Set: all randomized participants who received ≥1 vaccine or control dose.
Note: Adverse reaction data were collected on the electronic diary (e-Diary) by participants and those collected on the eCRF indicated as solicitated adverse reactions.
n=# of participants with specified reaction
N = number of exposed participants who submitted any data for the event, percentages are based on n/N a: Fever - Grade 3: ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: >40.0°C >104.0°F
b: Headache – Grade 3: Significant; any use of Rx pain reliever or prevents daily activity; Grade 4: Requires E.R. visit or hospitalization
c: Fatigue, Myalgia, Arthralgia – Grade 3: Significant; prevents daily activity; Grade 4: Requires E.R. visit or hospitalization
d: Nausea/Vomiting – Grade 3: Prevents daily activity, requires outpatient intravenous hydration; Grade 4: Requires E.R. visit or hospitalization for hypotensive shock
e: Chills – Grade 3: Prevents daily activity and requires medical intervention; Grade 4: Requires E.R. visit or hospitalization

Unsolicited AEs

Unsolicited AEs from the November 11, 2020 data cutoff include safety data from participants who had at least 1 month of follow-up after dose 2 (76.7% of all participants) those who had at least 2 months of follow-up after dose 2 (25.3% of all participants). The median study duration following dose 2 was 7 weeks across study groups. Table 25 below shows unsolicited AEs reported through the first data cutoff. Treatment emergent adverse events (AEs) were defined as any event that occurred during the study and was not present before exposure (study vaccine or placebo), any event that occurred during the study and was not present before exposure, or any event already present that worsened after exposure. The following unsolicited adverse events were specified in the protocol:

- Unsolicited AEs observed or reported during the 28 days following each vaccine or placebo dose
- AEs leading to discontinuation from vaccination and/or study participation through Day 759 (study completion) or withdrawal from the study
- Serious adverse events and medically attended adverse events through Day 759 (study completion) or withdrawal from study

Determination of severity for all unsolicited AE were made by the investigators based on medical judgement and definitions of severity as mild, moderate, or severe.

The overall proportions of participants who reported an unsolicited adverse event were generally similar, with numerically slightly higher rates of unsolicited AEs in the vaccine group compared to placebo group for some categories of unsolicited nonserious AEs.

Table 25. Summary of Unsolicited AEs Regardless of Relationship to the Investigational Vaccine, Through 28 Days After Any Vaccination, Study 301, Safety Set

Event Type	Nov 11 Dataset[a] mRNA-1273 (N=15184) n (%)	Nov 11 Dataset[a] Placebo (N=15165) n (%)	Nov 25 Dataset[b] mRNA-1273 (N=15185) n (%)	Nov 25 Dataset[b] Placebo (N=15166) n (%)
All unsolicited AEs	3325 (21.9)	2949 (19.4)	3632 (23.9)	3277 (21.6)
Medically-attended	1215 (8.0)	1276 (8.4)	1372 (9.0)	1465 (9.7)
Severe unsolicited AEs	216 (1.4)	190 (1.3)	234 (1.5)	202 (1.3)
Leading to discontinuation from study vaccine	41 (0.3)	71 (0.5)	50 (0.3)	80 (0.5)
Serious	82 (0.5)	86 (0.6)	93 (0.6)	89 (0.6)
Death	2 (<0.1)	3 (<0.1)	2 (<0.1)	3 (<0.1)

Source:
Abbreviation: AE = adverse event.
Note: An AE is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure. Percentages were based on the number of safety participants.
[a] EUA request (interim analysis)-November 11 2020
[b] Primary efficacy analysis-November 25, 2020

Unsolicited Adverse Events

The table below shows rates of unsolicited AEs that occurred within 28 days of any vaccination and at rates of ≥1% in the vaccine group through the November 11, 2020 data cutoff. The proportion of vaccine recipients who reported an unsolicited AE was 21.9% (3325 participants) compared to 19.4% of placebo participants. A higher frequency of unsolicited adverse events was reported in the vaccine group compared to placebo group and was primarily attributed to local and systemic reactogenicity following vaccination.

Table 26. Unsolicited Adverse Events Occurring in ≥1% of Vaccine Group Participants, by MedDRA Primary System Organ Class and Preferred Term (Safety Analysis Set)[a]

System Organ Class Preferred Term	Vaccine N=15184 n (%) Any	Vaccine N=15184 n (%) Severe	Placebo N=15165 n (%) Any	Placebo N=15165 n (%) Severe
Infections and infestations	521 (3.4)	13 (<0.1)	621 (4.1)	25 (0.2)
Vascular disorders	149 (1.0)	28 (0.2)	138 (0.9)	39 (0.3)
Nervous system disorders	624 (4.1)	27 (0.2)	552 (3.6)	21 (0.1)
Headache	435 (2.9)	19 (0.1)	409 (2.7)	13 (<0.1)
Respiratory, thoracic and mediastinal disorders	480 (3.2)	8 (<0.1)	522 (3.4)	9 (<0.1)
Cough	148 (1.0)	1 (<0.1)	143 (0.9)	1 (<0.1)

Injury, poisoning and procedural complications	238 (1.6)	16 (0.1)	262 (1.7)	13 (<0.1)

Source: Sponsor's Tables 14.3.1.8.1 and 14.3.1.17.1
n (%)=number (percentage) of participants reporting the adverse event at least once
[a] EUA request (interim analysis): November 11, 2020 data cutoff.

Unsolicited AEs considered related by the investigator to study vaccination were reported by 7.4% of vaccine recipients and 4.0% of placebo recipients. The proportion of participants who reported severe unsolicited AEs was 1.4% following any vaccine dose (275 participants) and 1.3% following any placebo dose (225 participants). The most frequently reported severe AEs that occurred in greater numbers of vaccine than placebo recipients were headache, myalgia, arthralgia, injection site erythema, and injection site pain (Table 26).

Medically attended adverse events (MAAE) from dose 1 through 28 day following any dose were reported for 8.0% of participants in the vaccine group (1,839 events in 1,215 participants) and 8.4% of those in the placebo group (1,837 events in 1,276 participants). The majority of these events were considered not related to study vaccinations and were primarily attributed to local and systemic reactogenicity following vaccinations.

FDA conducted standard MedDRA queries (SMQs) using FDA-developed software to evaluate for constellations of unsolicited adverse events with onset following dose 1 through the November 11, 2020 cutoff. The SMQs were conducted on adverse event Preferred Terms that could represent various conditions, including but not limited to allergic, neurologic, inflammatory, and autoimmune disorders. FDA assessment of additional safety data accrued through the November 25, 2020 cutoff is ongoing, though specific SMQ of adverse events of clinical interest were assessed.

A SMQ evaluating lymphadenopathy-related events (including injection site lymphadenopathy, lymph node pain, and lymphadenitis) through the November 25, 2020 data cut demonstrated a numerical imbalance across study groups, with 1.1% of vaccine recipients (191 events in 173 vaccine recipients) compared to 0.63% of placebo recipients (109 events in 95 participants) reporting such events in the Safety Set. The rates reported in the older cohort (≥65 years) were 0.74% (28 events in 28 participants) in vaccine recipients compared to 0.35% (16 events in 13 participants) in placebo recipients. The rates reported in the younger cohort (18-64 years) were 1.3% (163 events in 145 participants) in vaccine recipients and 0.72% (93 events in 82 participants) in placebo recipients. These events support a plausible relationship to study vaccination and were also reported in the evaluation of solicited local adverse reactions. Local axillary swelling/tenderness was reported in approximately 19% of participants during the 7 days following any dose in the Solicited Safety Set. The median duration following any dose was 1 to 2 days, and <1% reported Grade 3 axillary swelling/tenderness.

A SMQ evaluating hypersensitivity-related adverse events through the November 25, 2020 data cutoff demonstrated a numerical imbalance across study groups, with 1.5% of vaccine recipients (258 events in 233 participants) and 1.1% of placebo recipients (185 events in 166 participants) reporting such events in the Safety Set. In the older cohort (age ≥65 years) which

comprised 24.8% of the Safety Set, the rates of hypersensitivity were 1.8% (74 events in 68 participants) in vaccine recipients and 1% (45 events in 38 participants) in placebo recipients. In the younger age cohort (18-64 years), the rates were 1.5% (184 events in 165 participants) in vaccine recipients compared to 1.1% (140 events in 128 participants). Overall, the most frequently reported AEs in the hypersensitivity SMQ were injection site rash (0.24% vaccine, 0.01% placebo), injection site urticaria (0.1% vaccine, 0% placebo), and rash maculo-papular (0.07% vaccine, 0.01% placebo). There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine.

A query of specific adverse events of clinical interest in the Safety Set through November 25, 2020 demonstrated a small imbalance in the number of participants reporting Bell's palsy (facial paralysis), with 3 vaccine recipients and 1 placebo recipient reporting this MAAE. One case of Bell's palsy in the vaccine group was considered a SAE; a 67-year-old female with diabetes was hospitalized for stroke due to new facial paralysis 32 days after vaccination. This case was reported as resolving. Another Bell's palsy case in the vaccine group occurred 28 days after vaccination in a 30-year-old female who reported an upper respiratory infection 27 days prior to onset of her facial paralysis. This case was reported as resolved. An additional case of Bell's palsy in the vaccine group was reported with the primary analysis safety data (November 25, 2020 data cutoff) and occurred 22 days after vaccination in a 72-year-old female; this event was still ongoing at the time of safety report. The case in the placebo group, reported as resolving, occurred 17 days post injection in a 52-year-old-male. Causality assessment is confounded by predisposing factors in these participants. However, considering the temporal association and biological plausibility, a potential contribution of the vaccine to the manifestations of these events of facial palsy cannot be ruled out. FDA will recommend surveillance for cases of Bell's palsy with deployment of the vaccine into larger populations. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of adverse events, including other neurologic, neuro-inflammatory, and thrombotic events, that would suggest a causal relationship to the Moderna COVID-19 vaccine.

Immediate Adverse Events

Immediate solicited reactions occurring within 30 minutes of vaccination were infrequent and there does not appear to be an imbalance between the treatment groups. Review of unsolicited AEs that occurred within 30 minutes of vaccination demonstrated comparable rates across study groups (0.6% vaccine, 0.6% placebo), and none of the events reported in the vaccine group were considered serious.

Study Withdrawals due to an Adverse Event (Safety Set)

Adverse events that led to discontinuation of vaccination were reported in 0.3% in the vaccine group and 0.5% in the placebo group. Following the November 25, 2020 cutoff, 4 participants were withdrawn from the study due to an adverse event (2 vaccine recipients and 2 placebo recipients). The two AEs reported in the vaccine group were acute pancreatitis and road traffic accident, and the two AEs reported in the placebo group were incarcerated hernia and duodenal ulcer hemorrhage. FDA's review of data through this latter time point is ongoing.

Serious Adverse Events

Deaths

As of December 3, 2020, 13 deaths were reported (6 vaccine, 7 placebo). Two deaths in the vaccine group were in participants >75 years of age with pre-existing cardiac disease; one

participant died of cardiopulmonary arrest 21 days after dose 1, and one participant died of myocardial infarction 45 days after dose 2. Another two vaccine recipients were found deceased at home, and the cause of these deaths is uncertain: a 70-year-old participant with cardiac disease was found deceased 57 days after dose 2, and a 56-year-old participant with hypertension, chronic back pain being treated with opioid medication died 37 days after dose 1 (The official cause of death was listed as head trauma). One case was a 72-year-old vaccine recipient with Crohn's disease and short bowel syndrome who was hospitalized for thrombocytopenia and acute kidney failure due to obstructive nephrolithiasis 40 days after dose 2 and developed complications resulting in multiorgan failure and death. One vaccine recipient died of suicide 21 days after dose 1. The placebo recipients died from myocardial infarction (n=3), intra-abdominal perforation (n=1), systemic inflammatory response syndrome in the setting of known malignancy (n=1), COVID-19 (n=1), and unknown cause (n=1). These deaths represent events and rates that occur in the general population of individuals in these age groups.

Non-fatal Serious Adverse Events

Among participants who received at least one dose of vaccine or placebo (N=30,351), the proportion of participants who reported at least one SAE from dose 1 to the primary analysis cutoff date (November 25, 2020) was 1% in the mRNA-1273 group and 1% in the placebo group. The most common SAEs occurring at higher rates in the vaccine group than the placebo group were myocardial infarction (0.03% in vaccine group, 5 cases vs. 3 cases in placebo group), cholecystitis (0.02% in vaccine group, 3 cases vs. 0 cases in placebo group), and nephrolithiasis (0.02% in vaccine group, 3 cases vs. 0 cases in placebo group). The small numbers of cases of these events do not suggest a causal relationship. The most common SAEs occurring at higher rates in the placebo arm than the vaccine arm, aside from COVID-19 (0.1% in placebo group), were pneumonia (0.05% in placebo group) and pulmonary embolism (0.03% in placebo group). Occurrence of other SAEs, including cardiovascular SAEs, were otherwise balanced between treatment groups.

As of November 25, 2020, 7 SAEs (4.8%) in the mRNA-1273 group and 5 (3.3%) in the placebo group were assessed by the investigator as related to study vaccination (Table 27). Of the 7 SAEs in the mRNA-1273 group, the Sponsor assessed 4 as related and 3 as unrelated to the vaccine.

Table 27. SAEs Considered Related by Investigator

Investigational Product	SAE	Onset (days after last dose)	Demographics/ Risk factors	Resolution	Related per Investigator/ Moderna
mRNA-1273	Intractable nausea and vomiting	1	65 F; history of headaches and severe nausea requiring hospitalization	Resolved	Yes/Yes
mRNA-1273	Facial swelling	1	46 F; dermal filler cosmetic injection 6 months prior	Resolved	Yes/Yes
mRNA-1273	Facial swelling	2	51 F; dermal filler cosmetic injection 2 weeks prior	Resolved	Yes/Yes
mRNA-1273	Rheumatoid arthritis	14	57 M; hypothyroid	Unresolved	Yes/Yes
mRNA-1273	Dyspnea with exertion, peripheral edema	8	66 F; diabetes, hypertension	Resolving	Yes/No

Investigational Product	SAE	Onset (days after last dose)	Demographics/ Risk factors	Resolution	Related per Investigator/ Moderna
mRNA-1273	Autonomic dysfunction	24	46 F; hypothyroid; possible sinus infection	Unresolved	Yes/No
mRNA-1273	B-cell lymphocytic lymphoma	31	75 F; history of metastatic lung cancer, breast cancer	Unresolved	Yes/No
Placebo	Polymyalgia rheumatica	15	83 M; chronic low back pain	Resolving	Yes/Yes
Placebo	Facial swelling, paresthesia, anxiety	7	41 F; dental procedure 2 weeks prior	Resolved	Yes/No
Placebo	Procedural hemorrhage	16	52 M; aortic stenosis, hyperlipidemia; aspirin intake	Resolved	Yes/No
Placebo	Pulmonary embolism	24	59 M; smoking	Unresolved	Yes/No
Placebo	Pneumonia and myocardial infarction	29	70 M; coronary artery disease, chronic kidney disease, diabetes	Resolved	Yes/No

There was one event of lip angioedema 2 days after vaccination in a 29-year-old female participant in the vaccine group which was classified as medically significant but not considered an SAE. The participant has a history of dermal filler injection in the lips (unknown how long prior to vaccination). She reported having a similar reaction after receipt of an influenza vaccine in the past. Taken in context with the SAEs of facial swelling which occurred in 2 participants who had previous history of cosmetic filler injections, it is possible the localized swelling in these cases is due to an inflammatory reaction from interaction between the immune response after vaccination and the dermal filler. This phenomenon has been reported after natural infection (e.g., after an influenza-like illness).

In FDA's opinion following review of the narratives, 3 SAEs are considered likely related, including the one report of intractable nausea/vomiting and 2 reports of facial swelling. The possibility that the vaccine contributed to the SAE reports of rheumatoid arthritis, peripheral edema/dyspnea with exertion, and autonomic dysfunction cannot be excluded. The vaccine was unlikely to have contributed to the other SAEs assessed by the investigator as related. As described in detail in a previous section, there was one report of Bell's palsy in the vaccine arm which occurred 32 days after vaccination; both the investigator and the Sponsor assessed this event as unrelated to the study vaccine, but in FDA's assessment a causal relationship cannot be definitively excluded.

Subgroup Analyses

There were no specific safety concerns identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection, and occurrence of solicited, unsolicited, and serious adverse events in these subgroups were generally consistent with the overall study population.

Pregnancies

Study participants of childbearing potential were screened for pregnancy prior to each vaccination, with a positive test resulting in exclusion or discontinuation from study vaccination. The study is collecting outcomes for all reported pregnancies that occur after vaccination, or

before vaccination and not detected by pre-vaccination screening tests. Thirteen pregnancies were reported through December 2, 2020 (6 vaccine, 7 placebo). Study vaccination occurred prior to the last menstrual period (LMP) in 5 participants (2 vaccine, 3 placebo), within 30 days after LMP in 5 participants (2 vaccine, 3 placebo), >30 days after LMP in 2 participants (1 vaccine, 1 placebo), and date of LMP not known in 1 participant (1 vaccine, 0 placebo). Unsolicited AEs related to pregnancy include a case of spontaneous abortion and a case of elective abortion, both in the placebo group. One participant in the placebo group is lost to follow-up. Pregnancy outcomes are otherwise unknown at this time.

A combined developmental and perinatal/postnatal reproductive toxicity study of mRNA-1273 in rats was submitted to FDA on December 4, 2020. FDA review of this study concluded that mRNA1273 given prior to mating and during gestation periods at dose of 100 µg did not have any adverse effects on female reproduction, fetal/embryonal development, or postnatal developmental except for skeletal variations which are common and typically resolve postnatally without intervention.

Safety Summary

The information provided by the Sponsor was adequate for review and to make conclusions about the safety of the mRNA-1273 vaccine in the context of the proposed indication and population for intended use under EUA. The number of participants in the Phase 3 safety population (N=30,350; 15,184 vaccine,15,165 placebo) meets the expectations described in FDA's Guidance on Development and Licensure of Vaccines to Prevent COVID-19 for efficacy. The initial EUA request was based on data from the pre-specified interim analysis (November 11, 2020 data cutoff) with a median follow-up duration of 7 weeks after dose 2; this interim analysis data is the primary basis of this EUA review and conclusions. Data and analyses from a November 25, 2020 data cut with a median duration of at least 2 months follow-up after completion of the 2-dose primary vaccination series was submitted as an amendment to the EUA request on December 7, 2020. The FDA has not independently verified the complete safety data from the primary analysis, aside from all new deaths (including those reported through December 3, 2020) and SAEs. No new safety concerns have been identified. The rates and types of solicited adverse reactions and unsolicited adverse events are unlikely to change significantly with an additional 2 weeks of follow-up. The totality of the data package submitted in the EUA request meets the Agency's expectations on the minimum duration of follow-up.

Local site reactions and systemic solicited events after vaccination were frequent and mostly mild to moderate. The most common solicited adverse reactions were injection site pain (91.6%), fatigue (68.5%), headache (63.0%), muscle pain (59.6%), joint pain (44.8%), and chills (43.4%); 0.2% to 9.7% were reported as severe, with severe solicited adverse reactions being more frequent after dose 2 than after dose 1 and generally less frequent in adults ≥65 years of age as compared to younger participants. Among adverse events of clinical interest, lymphadenopathy was reported in 173 participants (1.14%) in the vaccine group and 95 participants (0.63%) in the placebo group. There was a numerical imbalance in hypersensitivity adverse events across study groups, with 1.5% of vaccine recipients and 1.1% of placebo recipients reporting such events in the Safety Set. There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine. Throughout the safety follow-up period to date, there has been three reports of Bell's palsy in the vaccine group and one in the placebo group. Currently available information is insufficient to determine a causal relationship with the vaccine. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of adverse events (including other neurologic, neuro-inflammatory, and thrombotic events) that would suggest a causal relationship to mRNA-

1273.

As of December 3, 2020, there were a total of 13 deaths reported in the study (6 vaccine, 7 placebo). These deaths represent events and rates that occur in the general population of individuals in these age groups. The frequency of non-fatal serious adverse events was low and without meaningful imbalances between study arms (1% in the mRNA-1273 group and 1% in the placebo group). The most common SAEs in the vaccine group which were numerically higher than the placebo group were myocardial infarction (0.03%), cholecystitis (0.02%), and nephrolithiasis (0.02%), although the small numbers of cases of these events do not suggest a causal relationship. The most common SAEs in the placebo arm which were numerically higher than the vaccine arm, aside from COVID-19 (0.1%), were pneumonia (0.05%) and pulmonary embolism (0.03%).

6. Sponsor's Plans for Continuing Blinded, Placebo-Controlled Follow-Up

ModernaTX expects that participants, including approximately 25% who are healthcare workers, may request unblinding to receive mRNA-1273 or another vaccine potentially available under EUA external to the trial. More extensive participant-driven crossover would be expected to alter the composition of the trial population, with greatly increased participant dropout due to a large proportion of participants belonging to priority vaccination groups desiring to be vaccinated with vaccine made available under EUA. ModernaTX is evaluating the opportunity to amend the protocol to proactively reconsent participants who received placebo to be offered mRNA-1273 vaccination and to remain in the trial, enabling ModernaTX to continue to collect the relevant safety and effectiveness data over the entire two years of follow-up while increasing the likelihood of retaining participants on trial. Adverse events among those vaccinated within the trial will be captured, regardless of the treatment group to which the participants were originally allocated, over the entire follow-up period of 24 months.

7. Pharmacovigilance Activities

The Sponsor submitted a Pharmacovigilance Plan to monitor safety concerns that could be associated with the Moderna COVID-19 Vaccine. The Sponsor identified vaccine-associated enhanced disease (which includes but is not limited to vaccine-associated enhanced respiratory disease) and anaphylactic reactions (including anaphylaxis) as important potential risks. Use in the pediatric population, use in pregnant and breast-feeding women, immunogenicity in participants with immunosuppression, concomitant administration with non-COVID vaccines, long-term safety and long-term effectiveness are areas the Sponsor identified as missing information.

The Sponsor will conduct both passive and active surveillance activities for continued vaccine safety monitoring. Passive surveillance activities will include submitting spontaneous reports of the following events to the Vaccine Adverse Event Reporting System (VAERS) within 15 days:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in adults
- Cases of COVID-19 that result in hospitalization or death

The Sponsor will also conduct periodic aggregate review of safety data and proposed to submit periodic safety reports at quarterly intervals, or at another interval specified by FDA. FDA has

requested that periodic reports be submitted monthly. Each periodic safety report is required to contain descriptive information which includes:

- A narrative summary and analysis of adverse events submitted during the reporting interval, including interval and cumulative counts by age groups, special populations (e.g., pregnant women), and adverse events of special interest
- Newly identified safety concerns in the interval
- Actions taken since the last report because of adverse experiences (e.g., changes made to Vaccination Provider fact sheets, changes made to studies or studies initiated)

Sponsor studies will include completion of long-term follow-up from ongoing clinical trials as well as the following three planned surveillance studies.

- Pregnancy Cohort: The Sponsor plans to establish a passive pregnancy registry to monitor vaccination during pregnancy within populations expected to receive the vaccine under EUA, and to submit a protocol for FDA review and approval.

- Active Follow-up for Safety: This study is an active safety surveillance activity conducting retrospective analyses of medical and pharmacy claims data to address three objectives; estimation of background rates of 23 prespecified adverse events of special interest (AESI), descriptive analyses of observed versus expected rates, and self-controlled risk interval analyses that will be conducted if certain criteria are met from the descriptive analyses. The planned study duration is through December 2022.

- Real World Effectiveness Study: This study is a prospective cohort study to be conducted at Kaiser Permanente Southern California to evaluate vaccine effectiveness in preventing the following outcomes: laboratory confirmed and clinical COVID-19 infection, hospitalization, and mortality for COVID-19. Vaccinated participants will receive Moderna COVID-19 Vaccine between January 1, 2021 and December 31, 2021, and the comparator group will be age matched, unvaccinated KPSC members. The planned study duration is through December 31, 2023.

FDA will provide feedback on these studies after further review of protocols once submitted by the Sponsor.

Reporting to VAERS and ModernaTX, Inc.

Providers administering the Moderna COVID-19 Vaccine must report to VAERS (as required by the National Childhood Vaccine Injury Act) and to ModernaTX the following information associated with the vaccine of which they become aware:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in adults
- Cases of COVID-19 that result in hospitalization or death

Additional VAERS Reporting

An additional source of VAERS reports will be through a program administered by the CDC known as v-safe. V-safe is a smartphone-based opt-in program that uses text messaging and web surveys from CDC to check in with vaccine recipients for health problems following COVID-19 vaccination. The system also will provide telephone follow-up to anyone who reports

medically significant (important) adverse events. Responses indicating missed work, inability to do normal daily activities, or that the recipient received care from a doctor or other healthcare professional will trigger the VAERS Call Center to reach out to the participant and collect information for a VAERS report, if appropriate.

8. Benefit/Risk Assessment in the Context of Proposed Indication and Use Under EUA

8.1 Known Benefits

The known benefits among recipients of the proposed vaccine relative to placebo are:

- Reduction in the risk of confirmed COVID-19 occurring at least 14 days after the second dose of vaccine
- Reduction in the risk of confirmed severe COVID-19 occurring at least 14 days after the second dose of vaccine

The 2-dose vaccination regimen was highly effective in preventing PCR-confirmed COVID-19 occurring at least 14 days after receipt of the second dose. Secondary efficacy analyses showed consistency with outcomes in the primary efficacy analysis; the vaccine was effective in preventing COVID-19 using a less restrictive definition of the disease and considering all cases starting 14 days after the first injection. Efficacy findings in the interim analysis were also consistent across various subgroups, including racial and ethnic minorities, participants ages 65 years and older, and those at risk for severe COVID-19 disease due to obesity, diabetes, cardiac disease, liver disease, chronic lung disease, mild to severe asthma, and infection with HIV, although the efficacy estimate in participants ages 65 years and older was slightly lower in the primary efficacy analysis.

8.2 Unknown Benefits/Data Gaps

Duration of protection

As the interim and final analyses have a limited length of follow-up, it is not possible to assess sustained efficacy over a period longer than 2 months.

Effectiveness in certain populations at high-risk of severe COVID-19

Although the proportion of participants at high risk of severe COVID-19 is adequate for the overall evaluation of safety in the available follow-up period, the subsets of certain groups such as immunocompromised individuals (e.g., those with HIV/AIDS) are too small to evaluate efficacy outcomes.

Effectiveness in individuals previously infected with SARS-CoV-2

Limited data suggest that individuals with prior SARS-CoV-2 infection can be at risk of COVID-19 (i.e., re-infection) and may benefit from vaccination. Regarding the benefit of the mRNA-1273 for individuals with prior infection with SARS-CoV2, participants with a known history of SARS-CoV-2 infection were excluded from the Phase 3 study, and there was only one case of COVID-19 among study participants with positive SARS-COV-2 infection status at baseline. Thus, the study was not designed to assess the benefit in individuals with prior SARS-CoV-2 infection.

Effectiveness in pediatric populations

No efficacy data are available from participants ages 17 years and younger.

Future vaccine effectiveness as influenced by characteristics of the pandemic, changes in the virus, and/or potential effects of co-infections

The study enrollment and follow-up occurred during the period of July 27, 2020 to November 21, 2020, in sites across the United States. The evolution of the pandemic characteristics, such as increased attack rates, increased exposure of subpopulations, as well as potential changes in the virus infectivity, antigenically significant mutations to the S protein, and/or the effect of co-infections may potentially limit the generalizability of the efficacy conclusions over time. Continued evaluation of vaccine effectiveness following issuance of an EUA and/or licensure will be critical to address these uncertainties.

Vaccine effectiveness against asymptomatic infection

Data are limited to assess the effect of the vaccine in preventing asymptomatic infection as measured by detection of the virus and/or detection of antibodies against non-vaccine antigens that would indicate infection rather than an immune response induced by the vaccine. Additional evaluations will be needed to assess the effect of the vaccine in preventing asymptomatic infection, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against long-term effects of COVID-19 disease

COVID-19 disease may have long-term effects on certain organs, and at present it is not possible to assess whether the vaccine will have an impact on specific long-term sequelae of COVID-19 disease in individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 should translate to overall prevention of COVID-19-related sequelae in vaccinated populations, though it is possible that asymptomatic infections may not be prevented as effectively as symptomatic infections and may be associated with sequelae that are either late-onset or undetected at the time of infection (e.g., myocarditis). Additional evaluations will be needed to assess the effect of the vaccine in preventing long-term effects of COVID-19, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against mortality

A larger number of individuals at high risk of COVID-19 and higher attack rates would be needed to confirm efficacy of the vaccine against mortality. However, non-COVID vaccines (e.g., influenza) that are efficacious against disease have also been shown to prevent disease-associated death.[13-16] Benefits in preventing death should be evaluated in large observational studies following authorization.

Vaccine effectiveness against transmission of SARS-CoV-2

Data are limited to assess the effect of the vaccine against transmission of SARS-CoV-2 from individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 may translate to overall prevention of transmission in populations with high enough vaccine uptake, though it is possible that if efficacy against asymptomatic infection were lower than efficacy against symptomatic infection, asymptomatic cases in combination with reduced mask-wearing and social distancing could result in significant continued transmission. Additional evaluations including data from clinical trials and from vaccine use post-authorization will be needed to assess the effect of the vaccine in preventing virus shedding and transmission, in particular in individuals with asymptomatic infection.

8.3 Known Risks

The vaccine elicited increased local and systemic adverse reactions as compared to those in the placebo arm, usually lasting a few days. The most common solicited adverse reactions were pain at injection site (91.6%), fatigue (68.5%), headache (63.0%), muscle pain (59.6%), joint pain (44.8%), and chills (43.4%). Adverse reactions characterized as reactogenicity were generally mild to moderate; 0.2% to 9.7% of these events were reported as severe, with severe solicited adverse reactions being more frequent after dose 2 than after dose 1 and generally less frequent in older adults (≥65 years of age) as compared to younger participants. Among reported unsolicited adverse events, lymphadenopathy occurred much more frequently in the vaccine group than the placebo group and is plausibly related to vaccination. The number of participants reporting hypersensitivity-related adverse events was numerically higher in the vaccine group compared with the placebo group (258 events in 233 participants [1.5%] vs. 185 events in 166 participants [1.1%]). There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine.

Serious adverse events, while uncommon (1.0% in both treatment groups), represented medical events that occur in the general population at similar frequency as observed in the study. Of the 7 SAEs in the mRNA-1273 group that were considered as related by the investigator, FDA considered 3 as related: intractable nausea and vomiting (n=1), facial swelling (n=2). For the serious adverse events of rheumatoid arthritis, peripheral edema/dyspnea with exertion, and autonomic dysfunction, a possibility of vaccine contribution cannot be excluded. For the event of B-cell lymphoma, an alternative etiology is more likely. An SAE of Bell's palsy occurred in a vaccine recipient, for which a causal relationship to vaccination cannot be concluded at this time.

No specific safety concerns were identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection.

8.4 Unknown Risks/Data Gaps

Safety in certain subpopulations

There are currently insufficient data to make conclusions about the safety of the vaccine in subpopulations such as children less than 18 years of age, pregnant and lactating individuals, and immunocompromised individuals.

FDA review of a combined developmental and perinatal/postnatal reproductive toxicity study of mRNA-1273 in female rats concluded that mRNA1273 given prior to mating and during gestation periods at dose of 100 µg did not have any effects on female reproduction, fetal/embryonal development, or postnatal developmental except for skeletal variations which are common and typically resolve postnatally without intervention

Adverse reactions that are very uncommon or that require longer follow-up to be detected

Following authorization of the vaccine, use in large numbers of individuals may reveal additional, potentially less frequent and/or more serious adverse events not detected in the trial safety population of approximately 30,000 participants over the period of follow-up at this time. Active and passive safety surveillance will continue during the post-authorization period to detect new safety signals.

Although the safety database revealed an imbalance of cases of Bell's palsy (3 in the vaccine group and 1 in the placebo group), causal relationship is less certain because the number of cases was small and not more frequent than expected in the general population. Further signal detection efforts for these adverse events will be informative with more widespread use of the vaccine.

Vaccine-enhanced disease

Available data do not indicate a risk of vaccine-enhanced disease, and conversely suggest effectiveness against severe disease within the available follow-up period. However, risk of vaccine-enhanced disease over time, potentially associated with waning immunity, remains unknown and needs to be evaluated further in ongoing clinical trials and in observational studies that could be conducted following authorization and/or licensure.

10. Appendix A. Phase 1 and 2 Studies

Study DMID Protocol 20-0003

Study Design
DMID Protocol 20-0003 is an ongoing Phase 1, open-label, first-in-human, dose-ranging study to evaluate the safety and immunogenicity of mRNA-1273 in healthy adults 18 years of age and older. A total of 120 participants without risk factors for progression to severe COVID-19 were enrolled into one of 10 age and dose cohorts to receive 2 injections of 25 µg, 50 µg, 100 µg, or 250 µg of mRNA-1273 given 28 days apart. The study included 60 participants 18 through 55 years of age, 30 participants 56 through 70 years of age, and 30 participants 71 years and older. Participants will be followed safety and immunogenicity for 12 months after last vaccination.

Study Objectives/Endpoints Relevant to the EUA
The immunogenicity objectives are to evaluate the binding antibody (bAb) concentrations for spike IgG as measured by ELISA and neutralizing antibody (nAb) titers as measured by PsVNA for all dose levels at baseline and at various time points after vaccination. The study also evaluated T-cell responses elicited by the mRNA-1273 vaccine as assessed by an intracellular cytokine stimulation assay. All participants are followed for solicited adverse reactions through 7 days post each vaccination. Unsolicited AEs are collected through 28 days after each vaccination. All SAEs and medically attended adverse events are collected through the end of the study.

Statistical Analysis

No formal statistical hypothesis was tested in this study, and all results were descriptive.

Study Results

The study showed a dose response in participants across all age groups as measured by both binding and neutralizing antibodies after 2 doses. There was a comparable response between the 100-µg and 250-µg dose groups, and both were greater compared to the 25-µg group. The bAb and nAb levels seen after 2 doses of 100 µg or 250 µg of mRNA-1273 were similar in magnitude compared to those seen in pooled convalescent sera from patients recovered from COVID-19. All dose levels elicited CD4+ T-cell responses that were strongly biased toward expression of Th1 cytokines, with minimal Th2 cytokine expression. This Th1-dominant profile was clinically reassuring in terms of risk of developing vaccine-induced disease. These results, along with the interim safety data showing a lower incidence of reactogenicity in the 100ug group compared to the 250ug group, led to the selection of the 100ug dose to advance to Phase 2 and 3. Preliminary safety data from this Phase 1 study show a similar profile to that observed in the Phase 3 study. No SAEs or severe COVID-19 cases have been reported from this study as of November 16, 2020.

Study mRNA-1273-P201

Study Design
Study mRNA-1273-P201 is an ongoing phase 2a, randomized, observer-blind, placebo-controlled, dose-confirmation study to evaluate the safety, reactogenicity, and immunogenicity of mRNA-1273 in healthy adults 18 years and older. The study enrolled 600 participants, consisting of 300 participants 18 to <55 years old and 300 participants 55 years and older, who

were randomized equally to receive either 2 doses of 50ug of mRNA-1273, 100ug of mRNA-1273, or saline placebo given 28 days apart. Participants will be followed for safety and immunogenicity for 12 months post last vaccination.

Study Objectives/Endpoints Relevant to the EUA
The immunogenicity objectives are to evaluate the immunogenicity of 2 doses of mRNA-1273 at the 2 dose levels (50 µg and 100 µg) administered 28 days apart as assessed by level of bAb and by nAb titers at baseline and at various time points after vaccination. All participants are followed for solicited adverse reactions through 7 days post each vaccination. Unsolicited AEs are collected through 28 days after each vaccination. All SAEs and medically attended adverse events are collected through the end of the study.

Statistical Analysis

No formal statistical hypothesis was tested in this study and all results were descriptive.

Study Results

The immune response as assessed by bAb and nAb after 2 doses were comparable in the 50-µg and 100-µg dose groups, with an overall geometric mean fold rise (GMFR)>20-fold in bAB as measured by ELISA and >50-fold in nAb as measured by microneutralization assay at 28 days post-dose 2. In the 100-µg dose group, the older age cohort (≥55 years) had slightly lower bAb response when compared to the younger age cohort (18 to <55 years) at 28 days post-dose 2, but the nAb response was similar between both age groups

Safety profile was similar to that reported in the Phase 3 study. Laboratory evaluations (including complete blood count, liver function tests, kidney functions tests, and coagulation studies) were conducted for participants ≥55 years of age (N=100) at baseline and at 1 month after the second dose (Day 29, Day 57). According to narratives that the Sponsor provided to FDA on December 6, 2020, there were 2 participants in the 100-µg group who experienced Grade 3 decreases in hemoglobin (Grade 0 reported at baseline), but both Grade 3 values were within normal range and not clinically significant. The overall event rates were not provided.

As of December 6, 2020, there were 3 SAEs reported in the vaccine group: a 65-year-old participant with community acquired pneumonia 25 days after vaccination, a 72-year-old participant with arrhythmia after being struck by lightning 28 days after vaccination, and an 87-year-old participant with worsening of chronic bradycardia 45 days after vaccination. On FDA review of the narratives, none of these SAEs are assessed as related. There were no cases of severe COVID-19 reported in the study.

June 19, 2021

From: Robert W. Malone, MD, MS
357 Hebron Valley Rd,
Madison, VA 22727

To: Whom it may Concern

I am writing this letter to support Dr. Bridle's good character and his right to freely express his scientific opinion, which is backed up by the literature and well informed deductive reasoning.

I am a US-based physician and scientist with an extensive record of successful innovation in basic and applied science, pathology, molecular virology, immunology, vaccine development, biodefense, project management, clinical development, regulatory affairs, and bioethics. I have been working in this area since 1984, and have been through multiple outbreaks – usually supporting either pharmaceutical clients or the US Department of Defense. I have been granted "secret" clearance for the DoD. I played a key role in advancing the PHAC rVSV-ZEBOV Ebola vaccine candidate and engaging Merck in development, which resulted in the eventual licensure of this very important product of Canadian PHAC research.

I am also the original inventor of mRNA vaccines and DNA vaccines. This claim is substantiated by academic publications as well a large suite of US and worldwide patents with a filing date of 1989.

I have independently assessed most of the data which serves as the basis for Dr. Bridle's communications regarding safety risks associated with the COVID-19 genetic vaccines, concur with his findings, and have independently raised my concerns with the US FDA including speaking directly with CBER director Peter Marks.

I am particularly alarmed and surprised by the bioethical positions being taken by the government of Canada regarding these experimental – stage vaccines, and very surprised. I have always considered the government and people of Canada to be eminently reasonable, almost to a fault. These policies appear contrary to what I have been trained as the bedrock principles of clinical research/human subjects bioethics.

And then there is the censorship of legitimate academic discourse, which brings us back to the specific case of Dr. Bridle. In short, do his accusers have no shame? I am truly shocked. Again, this is contrary to everything I had ever believed about the people and culture of Canada. I guess I will need to re-think my assumptions about Canadian fundamental reasonableness – ey?

Furthermore, these attacks on him will make him a global martyr and amplify his message. Is that really good public policy?

RW Malone MD, MS
Consulting and Analytics for Biopharma

Your World is
Our World

Please stop. Think about what is going on here. This is not fair. This is not right. This is not proper. Dr. Bridle has examined the data available to him and has drawn reasonable conclusions about the meaning of that data in toto. He is not profiting from this. There are no financial conflicts of interests. He is not someone seeking fame and fortune. He is doing what he can, in good faith, to help protect the people of Canada and the world – and particularly the adolescents and children.

In sum, in regards to COVID-19, I find the general censorship of the government of Canada, the bioethical lapses, and this specific example involving Dr. Bridle to be particularly egregious, and inconsistent with all I had previously believed regarding the fundamental reasonableness and commitment to fairness of Canadian political and social culture.

Please stop politicizing science. The scientific process requires dissent and discussion to arrive at truth. This is a central tenant. Dr. Bridle has spoken truth as he sees it. Others may interpret the data differently. My assessment is very much aligned with that of Dr. Bridle. That does not make it right or wrong. Time will sort this out. But I am quite sure that the attempts to silence Dr. Bridle and damage his career and reputation are fundamentally wrong.

Regardless of your or my individual assessments and opinions, please let science and the scientific process resolve this. These attacks on the credibility of Dr. Bridle and his good faith efforts to provide an alert concerning safety signals associated with these vaccines are highly inappropriate and counterproductive. I suspect that history will not look back on this kindly. Canadians have not always been on the right side of history – witness the indigenous peoples. But in my experience they do try to do the right and proper thing.

So do the right thing here.

Sincerely

Robert W Malone, MD, MS

Thanks for the nice synopses of that misinformation. I've been dealing with damage control from the crap that he's been spewing for months, since I get a lot of questions from vets or the general population because I'm active in the area and on the Science Table. It's great to have someone with your immunological expertise critique the comments.

Byram aggressively accused me of threatening him earlier simply by saying generically at a dept meeting something like ("I'd just ask everyone to remember that words matter. People are scared and confused, and we need to think about how we communicate"). Hopefully he doesn't add drama for you, but I'm happy to back you up whenever I can. I've raised the issue before with the University to at least stop amplifying his messages by tweeting his interviews or putting things in the OVC Newsletter (but some things still get out. Academic freedom is different from the University needing to promote someone's views).

Surgery
UNIVERSITY OF TORONTO

Recently an editorial written by Dr. Lawrence Klotz, a urologist at the University of Toronto, was published in the European Journal of Urology. The editorial has received a lot of attention through social media due to the opinions expressed about gender and surgery, garnished through "reverberacy". We would like to make it clear that the opinions expressed in this editorial do not represent those of the Department of Surgery at the University of Toronto.

Our Department seeks to promote an environment where equity and diversity are core values, where gender, ethnic, and racial diversity shape the culture, academic mission, and policies. We believe that equity and diversity drive high quality patient care, education, and innovation in research. One does not grow at the expense of the other; we can simultaneously raise our standards for both inclusion and clinical productivity. Promoting gender equity, and academic excellence are rather synergistic than mutually exclusive. While we support the right to academic freedom of speech, we do feel it is necessary to establish that these sentiments are in direct contrast to the mission and value system

@TRyanGregory and @weese_scott
n not just a public statement saying we can agree to disagree. A emen that exp icitly says the views expressed are in direct contrast to lue

I guess it helps to have a mission & values against which to measure things.

10

They are talking about me in this thread. They have been trying very hard to get the U of G to make a public statement that they do not condone my messaging.

J Scott Weese @weese_scott · Aug 31
It's a matter of will (and ethics). That's all there is to it.

Good on UofT Surgery for addressing this. It's easier to ignore it and hope if goes away, but it's not right.

University's need to stop using the easy button.

T. Ryan Gregory @TRyanGregory · Aug 31
Huh. So an institution *can* take a public stance where a member makes inaccurate claims that are harmful to society. How about that, @glenpyle and @weese_scott? twitter.com/UofTSurgery/st...

Exactly the same here. Abuse and threats from the fans of the misinformation crowd. Horrible management of the pandemic by this institution. Pissing people off because leaders won't lead.

Drained is the generous description.

Well, it's happened.
Someone we know in our small town was defiantly anti-vax, got COVID and is now on a ventilator.
Using resources that could be used for someone else with less preventable health issues.
I hope they get better but man... what a silly tragic waste.

213 816 6.6K

J Scott Weese @weese_scott · 8h

And false information like this led to pregnant women avoiding vaccines, then ending up in icu with severe complications, dying or losing their babies.

The impact of COVID on pregnant women has been huge...and preventable.

J M Leitch @JMLeitch · 15h

"In May, Canadian vaccine researcher and viral immunologist Byram Bridle, of the Uni of Guelph, Ontario, warned listeners of a podcast that nursing babies whose mothers had been vaccinated were at risk of getting COVID spike proteins from her breast milk."

Dr. Scott Weese has ignored the official police warning to cease and desist in his ongoing public harassment of me. This also follows prior receipt of a letter from lawyer Rocco Galati that also requested that he cease and desist.

First, Dr. Weese Retweeted an old Tweet from Dr. Fisman to tell the public to link 'antivaxxers' to neo-Nazi white supremacists; he routinely tells the public that I am an 'antivaxxer' (despite the fact that I am a vaccinologist who has continued to publish pro-vaccine papers throughout the declared pandemic). Then he sent a public message that I am continuing to promote various conspiracies yet failed to provide any evidence against what I talked about. Note that he suggested that others could do the fact checking; he wasn't willing to any fact checking himself. There was no question that he aimed this libelous message that lacked any scientific backing at me since the link goes directly to my picture and name. He does this all the time; the essence of his messages are 'Dr. Bridle is lying and/or does not know what he is talking about; believe this because I [Dr. Weese] said so'. He constantly picks on my oral off-the-cuff messaging to lay audiences where I cannot show my references. Never does he tackle my written documentation that is packed with scientific data and references. I submitted an affidavit about COVID-19 issues this past week; it was 593 pages long and contained original data and 387 references. I do know what I am talking about and can back it up with a profound quantity of scientific data. Remarkably, Dr. Weese's messaging is in text and on-line where he has every opportunity to show people peer-reviewed scientific studies to back-up his messages. I have never publicly released Dr. Weese's name. I focus on debating the science and leave the people behind the science out of the discussions. This is how academic conduct is to be practiced. Of additional concern, Dr. Weese then posted a Tweet that confirms his knowledge of potential action against him. This series of Tweets demonstrate that he is challenging the warnings issued against him. There has been no change is his harassing behaviour. As this continues to progress, I am becoming increasingly more concerned about my safety. Dr. Weese is clearly trying to make a public link between me, lies, and white supremist neo-Nazis. This has the potential to incite public violence against me. I have talk about COVID-19 issues yesterday to an audience of ~800 people. It was at this event that the series of Tweets shown here were brought to my attention. Members of the public and fellow scientists are expressing a lot of concern about my safety as Dr. Weese's behaviours continue to go unchecked. If needed, I can call upon a huge number of members of the public and fellow scientists to testify to this fact in a court of law. I will not feel safe unless Dr. Weese's harassment of me is stopped. To be clear, it is my opinion that Dr. Weese should feel free to discuss science; but he needs to start showing the evidence himself. He is free to attack science with science; but needs to stop attacking the people who are serving as messengers of scientific evidence.

RE: Tortious and Criminal Harassment of My Client

TO: Scott J. Weese <jsweese@uoguelph.ca>

CC: Dean Wichtel <jwichtel@uoguelph.ca>

Dear Mr. Weese,

I represent Professor Bryam Bridle. It's come to my attention that at least since May 29th, 2021, when my client first became aware, up to the present, you have and continue to post derogatory and hateful messages with respect to my client on social media and elsewhere, which constitute not only defamation and online harassment but moreover, criminal conduct.

My client, by two separate emails, on May 31st, 2021, notified you that your remarks were disparaging, harmful and constituted harassment. He emphatically requested that the "harassment in the workplace needs to stop." You failed to do so. On the contrary, since then your harassment of my client has escalated in tone, tenor, and frequency.

Ironically, since your frivolous, vexatious defamatory allegations against my client, made to Dean Wichtel in your complaint, dated July 21st, 2021, you have posted nearly **daily** provocative and harassing comments undercutting and undermining your own allegations. My client has not had **any** in-person encounters with you in more than one year. Yet, you continually and repeatedly make false provocatory and abusive comments about my client inciting harassment and hate against him.

The University has been placed on notice, as of September 7th, 2021 (but even prior to that on June 2nd, 2021), by my client that your harassment of him must cease immediately. It has not. Therefore, this serves as your final notice to immediately cease and desist any direct or indirect reference to my client, in any form or forum, whatsoever.

This also serves as notice that my client will be initiating proceeding, both civil **and criminal** against your past and most recent and ongoing harassment unless you issue a public and clean apology forthwith.

Meeting Request

Jeffrey Wichtel <jwichtel@uoguelph.ca>
Sun 6/20/2021 2:44 PM

To: Byram Bridle <bbridle@uoguelph.ca>
Cc: Laurie Arnott <l.arnott@exec.uoguelph.ca>

Dear Byram,

I am in receipt of the workplace harassment complaint you submitted.

I have had an opportunity to review the complaint and the attached evidence submitted in support of it. As I understand it, the complaint involves comments attributed to the Drs. Scott Weese and Glen Pyle, faculty members at the University, that occurred on a third-party social media platform (Twitter). There is also reference to a website with your name as the domain name, the creator of which is unknown but is not alleged to be one of the Respondents, though you indicate that Dr. Pyle knows its creator.

I have also had an opportunity to consult with Faculty and Academic Staff Relations regarding the workplace harassment process and its definition, I have also had an opportunity to consult with Faculty and Academic Staff Relations regarding the workplace harassment process, its definition and the behaviour that constitutes harassment thereunder.

Can we schedule a meeting to discuss your complaint? I'm available between 2 and 4pm tomorrow (Monday) – so feel free to get back to me and choose a 30-minute timeslot between 2 and 4. Laurie Arnott will join me on the meeting. If that time does not work, please get back to me and we will find another. If it works, I'll send a Teams invitation for the elected time.

You mention impact on your mental and physical health as a result of the issue you bring forward in your complaint. We've spoken about EAP, but I want to remind you about this service as it can be very helpful. At our meeting we can also discuss the challenges that you indicate you are experiencing completing work.

Sincerely,

Jeff

Subject: Harassment

CAUTION: This email originated from outside the organization. Do not click on links or open attachments you do not trust.

Dear Cst. Bird,

I gave a talk about COVID-19-related matters to ~800 people at an in-person event yesterday. At that event, it was revealed to me that Dr. Scott Weese is continuing his harassment of me in an uninterrupted fashion, despite the repeated warnings (both from Rocco and the police). Members of the public are perceiving his harassment as escalating. In this case, they felt that he had designed his recent thread of Tweets to intentionally start trying to link me to white supremist neo-Nazi's. Having reviewed the Tweets myself, I tend to agree. Based on both public feedback and my own assessments, I am growing progressively more fearful about the potential for Scott's ongoing and uninterrupted public harassment of me to incite some kind of retribution against me. The specific nature of this current complaint is in the attached Powerpoint file. Can you please help put an end to this?

Sincerely,
Byram

The Importance Of Planning In Your Dating Journey

In the fast-paced world of dating, where apps and online connections have become the norm, it's easy to get caught up in the excitement of meeting new people and overlook the importance of planning your dating journey. However, approaching your dating journey with a sense of purpose and preparation can greatly enhance the experience, providing direction and clarity. It helps you set realistic expectations, manage your time effectively, and increase the likelihood of finding a meaningful connection. In this article, we will explore why planning is a crucial element in navigating the complex world of dating and how it can help you make the most out of your dating journey.

Understanding Your Dating Goals

Before you start swiping right or left, it's important to take some time to reflect on what you're looking for in a partner and what you want to achieve through dating. Are you looking for a long-term relationship, casual dating, or simply to have fun and meet new people? Understanding your dating goals will help you narrow down your options and focus on individuals who align with your objectives. It will also help you communicate your intentions clearly to potential partners, avoiding misunderstandings and wasted time.

Quality Over Quantity

In the age of online dating, it's easy to fall into the trap of mindlessly swiping through countless profiles in search of the perfect match. However, this approach often leads to superficial connections and burnout. Instead of aiming for quantity, focus on quality. Take the time to carefully review profiles, read between the lines, and look for genuine compatibility. By investing more time and effort into each potential connection, you increase the chances of finding someone who truly aligns with your values and interests.

Time Management

Dating can be a time-consuming endeavor, especially if you're actively engaging with multiple matches and attending numerous dates. Without proper planning, it can easily become overwhelming and interfere with other aspects of your life, such as work, hobbies, and spending time with friends and family. By setting aside dedicated time for dating activities and establishing boundaries, you can maintain a healthy balance and prevent dating from taking over your entire schedule.

Preparation and Research

Before going on a date, it's essential to do some preparation and research. This can help you feel more confident and knowledgeable during the interaction. Take the time to learn about your date's interests, hobbies, and recent activities. This information can serve as conversation starters and help you find common ground. Additionally, researching potential date ideas in advance can ensure that you have a memorable and enjoyable experience.

Planning can turn a simple meeting into a memorable experience. Choosing activities that interest both parties, such as attending a cooking class, hiking, or visiting an art exhibit, can lead to richer interactions. Shared experiences often foster a deeper connection than traditional dinner dates and can be a refreshing change from the norm.

Safety Considerations

Safety is paramount in the dating world. Planning ahead allows you to take necessary precautions, such as meeting in public places, informing a friend about your whereabouts, and setting boundaries. A considered approach to [illegible] ensures a safer experience, allowing you to relax and enjoy the date.

Budgeting for Dating

[illegible] Planning your dating budget in advance helps you avoid overspending and ensures that you can enjoy dates without financial stress. Whether you're treating yourself to a fancy dinner or opting for a budget-friendly activity, setting aside a portion of your income for dating purposes demonstrates responsibility and respect for your financial well-being.

Emotional Preparedness

Dating can be an emotional rollercoaster, and it's important to be prepared for the highs and lows. Planning ahead helps you manage your expectations, reduce anxiety, and approach each date with a clear mind. It allows you to focus on building genuine connections rather than getting caught up in the pressure of the moment.

Long-Term Perspective

[illegible] Planning your dating journey with a long-term perspective in mind can help you avoid impulsive decisions and stay true to your values. Planning allows you to identify your relationship goals and make choices that align with those goals, increasing the likelihood of finding a fulfilling and lasting partnership.

Reflecting and Adjusting

A planned dating journey includes reflection and adjustment. After each date or interaction, take time to consider what went well and what didn't. This evaluation allows you to refine your approach, learn from mistakes, and [illegible] your goals and values.

In Conclusion

[illegible] Planning your dating journey can [illegible] to [illegible] a partner who complements and enhances your life. Planning [illegible] about setting the stage for success. We're successful dates are not [illegible] but by enjoying the journey, learning as we go, and making [illegible] connections that could lead to lasting [illegible]

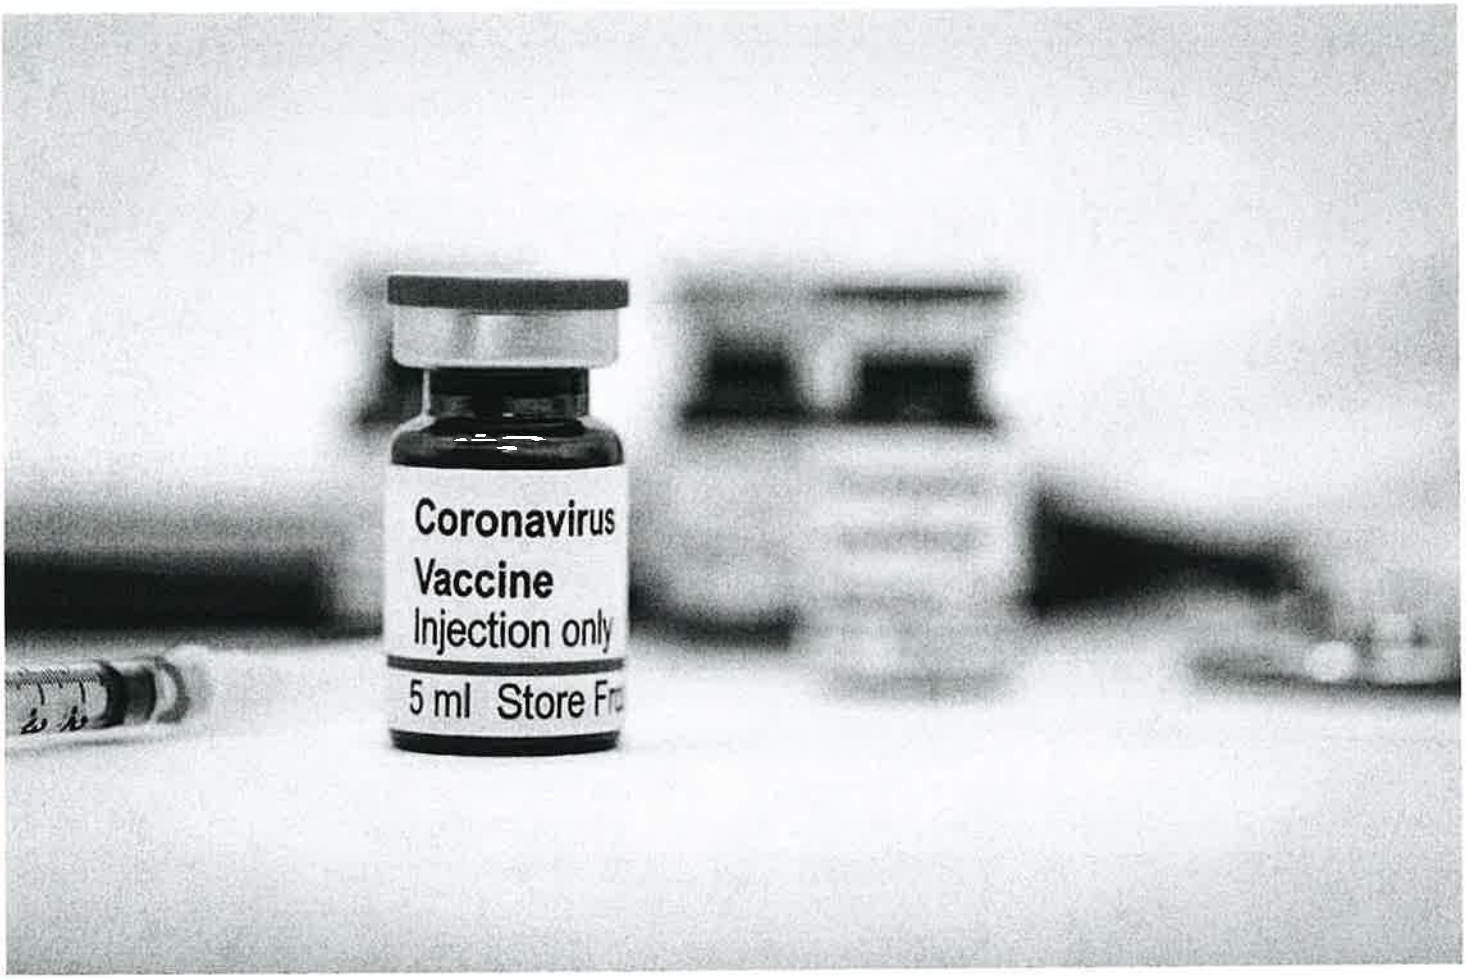
Lack of reviews of COVID vaccine raises concern with U of G expert

Anam Khan
Dec 15, 2020 7:00 AM



Stock photo

While the vaccine has arrived, some experts still have concerns.

The lack of scientific peer review raises some concerns, says Byram Bridle, a viral immunologist at the University of Guelph currently doing research to help prepare a vaccine for the next highly pathogenic coronavirus.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

immunology and I teach all of my students that good quality vaccines that have been vetted by the scientific community are, in my opinion, the best tool that we have in our medical toolbox and the most efficient ways to save a huge number of lives and a great form of preventative medicine," said Bridle.

The problem, he says, is we just don't know the long-term effects of this vaccine regardless of the new technology used.

"These vaccines have only been in people at most for half a year. And that's probably a bit liberal," says Bridle.

"That means that we can really only have absolute confidence in the safety of the vaccine up to about six months."

He says even when a vaccine takes years to develop, safety is still monitored when it goes out to the general public. But in this case, companies will be monitoring the results for at least the next two years once everyone gets vaccinated in order to collect safety data.

"This has never happened before. To collect that long term data. To know whether it continues to be safe a year after vaccination, two years after vaccination. We always had that data previously. We don't have it now and we will only get it as we monitor the rollout," says Bridle.

Bridle says many companies were developing a vaccine for MERS and were able to quickly switch over when COVID-19 came along.

Although these were made at a record-shattering pace, it's not quite the same as historical vaccines that had to start from scratch, says Bridle giving the example of the Ebola vaccine, which had several years of accumulated safety data before it was distributed to the public.

He says although the vaccines have met the milestones required for them to be approved by governing healthcare bodies, they are being rolled out without the phase 3 clinical trials being 100 per cent completed.

"I'm not judging the vaccines in any way, shape, or form. I'm just trying to state the facts," says Bridle.

"I have been asked many times personally would I take the vaccine right now? Personally, I don't feel 100 percent comfortable with it," says Bridle, adding that historically there have been side effects from vaccines despite taking some time to manifest.

"If there are any chronic issues with this, we're not going to be aware."

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

it needs to be approved by Health Canada, and second, the results from the phase 3 clinical trials need to be available – which really tells how the vaccine is working and what the safety profile looks like.

"I want to see that (phase 3 clinical trials) published and to go through rigorous scientific peer review."

On Dec. 9 Health Canada approved the Pfizer vaccine and stated that along with the Public Health Agency of Canada, it will closely monitor the safety vaccine once it hits the market, and also take necessary steps if there are safety concerns.

It also published documents about the vaccine ingredients, allergies, and possible side effects.

Regardless, Bridle gives the analogy of two toys priced the same but from different companies sitting on a shelf. One has a high-quality control system in place while the other has little to no quality control.

"When it comes to science, our quality control is the peer review process," says Bridle.

He says to publish the data, first of all, it has to go through the hands of reviewers to ensure the science is good and when it gets published, the entire scientific community has access to that data including scientists around the world who have no connection to that research and who have nothing to gain from that vaccine being marketed.

"Right now the phase 3 clinical trials have only been seen by the regulatory agencies. I trust they're doing their job. I also imagine that they're probably under the most enormous pressures that they've ever been in their careers in terms of trying to get a vaccine developed as soon as possible," says Bridle.

Nevertheless, he says decisions are being made by a relatively limited number of scientists.

"Yes, they have lots of expertise in the area but again, that's what I want to see personally and that's how it's happened in the past," says Bridle.

Bridle also talks about potential rare side effects which are normally not a big concern, however, because the goal is to roll the vaccine out on a global scale, Bridle says even very rare side effects could end up affecting a large number of people.

He gives the example of the two individuals who suffered an anaphylactic reaction in the UK the very first day the Pfizer vaccine rolled out.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

that once the vaccine is administered across the globe, it's possible hundreds of thousands of people have an anaphylactic reaction or something else.

After those allergic reactions, those with allergies were immediately told not to receive the vaccine.

"And then you can start asking the question, how many people with these allergies were enrolled in these trials? Well, because the data is not published, we don't know this," says Bridle adding that the vaccine is to only be administered in centers that have the equipment and expertise available to resuscitate people.

"The fact of the matter is, not everybody with a pre-existing condition could be tested in the phase 3 trials. Scientists have not been able to evaluate it and we've just simply had a very limited number of months in which this vaccine could be assessed and that only by those looking at the clinical trials."

"I personally cannot assure anybody 100 per cent that there are going to be no issues."

Controversial University of Guelph associate professor Byram Bridle has penned an open letter to U of G president Charlotte Yates calling for an end to the vaccine mandate.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

requested the 'favour of a reply' from Yates, asking that the response not be deferred to public health officials or a committee.

"Instead, a reply with the scientific rigour expected from a scholarly colleague rebutting each of my comments and addressing each question. Surely, you know the science underpinning COVID-19 vaccines inside and out by now," Bridle's letter stated.

U of G spokesperson Deirdre Healey confirmed the letter from Bridle, which was also published online, was received by Yates, and an appropriate response would be issued in a timely manner.

Bridle's letter states he could not be in stronger disagreement with Yates for forcing the current COVID-19 vaccines upon everyone who is part of the campus community.

He outlines those with naturally-acquired immunity don't need to be vaccinated and are at greater risk of harm if vaccinated and how testing for naturally-acquired immunity was a viable option but ignored.

The U of G was reporting recently that of those who submitted information, 99 per cent are partially or fully vaccinated and one per cent have requested or been granted an exemption.

The university said of the nearly 20,000 students who have provided information, 94 per cent are fully vaccinated and five per cent are partially vaccinated.

As well, 97 per cent of the faculty and staff who provided information are fully vaccinated and two per cent are partially vaccinated.

Bridle said in his letter: "My concern is not primarily for myself. I am using my case to highlight how wrong your vaccine mandate is.

"I am more concerned for the more vulnerable on our campus. I hold tenure, and if ever there was a time when this was important, it is now."

Bridle has spoken publicly about his concerns with the vaccine, which he says has caused harassment at the workplace.

Going against the university's mandate which requires all faculty to have both doses of a COVID-19 vaccine or a medical exemption, Bridle said he has been "banned" from campus for at least the next year.

"I can show proof of immunity against SARS-CoV-2 but you will not allow me to enter buildings. But someone else can show a receipt saying that someone saw two needles go into their arm and you

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

The letter reads: "I have found it necessary to write this so you can fully understand my perspective. With my life and that of my family, many friends and treasured colleagues being destroyed under your watch, I figure the least you can do is read and consider this very carefully. It is incredible to note that many, if not most, of my on-campus detractors have judged me without reading any of my scientific arguments or talking to me about them."

Attempts to reach Bridle for comment were unsuccessful.

A Toronto mother chose a controversial University of Guelph professor as her expert witness in a battle with the father over who should should have the final say in their son's vaccinations.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Court File No./N° du dossier du greffe : CV-22-00691880-0000
U (Toronto Superior Court of Justice / Cour supérieure de justice

peak of the pandemic and has been criticized by much of the scientific and medical community, was called as an expert by a mother fighting with the father of their 11-year-old son over who would control if and what vaccines the boy would receive.

The father wanted the boy to receive standard vaccinations and the COVID vaccine. The mother did not.

The court ruling determined the father, who does not have custody of the child, was best to make those decisions.

"In deciding this issue, the court must determine which parent is best capable of making vaccination decisions in their child's best interests," said Justice Sheilagh O'Connell in her written decision granting control to the father.

The child had COVID last February, reinforcing the father's quest to get him vaccinated for COVID.

The father's expert witness was Dr. Abdu Sharkawy, an internal medicine and infectious diseases specialist at the University Health Network. He testified that the 11 year old should receive the COVID vaccine at the appropriate time.

"Dr. Sharkawy also discussed the concerns raised by some, including the mother's proposed expert, about the MRNA technology used to create the vaccine. He explained that this technology is not new and that it has been around for many years," said the written judgment.

"Dr. Sharkawy's medical practice is at Toronto Western Hospital, where he has worked on the Covid ward and the Intensive Care Unit (ICU) attending Covid patients since the beginning of the pandemic. He is trained in pediatric infectious diseases. He has had extensive first-hand, front line "real world" experience treating Covid patients throughout the pandemic."

The judge noted that Sharkawy's opinions regarding vaccines for children are shared by numerous health organizations around the world.

While acknowledging that Bridle is an expert in his research field, she ruled he was not qualified to give expert opinion on this case.

"However ... the court does not accept that Dr. Bridle is qualified to give opinion evidence with respect to the safety and efficacy of the Covid-19 vaccine for children," the ruling states.

"Dr. Bridle acknowledged that he is not a medical doctor. He has never vaccinated a child, he has never treated a child or an adult suffering from a reaction to a vaccine, nor has he ever treated a child or an adult who is suffering from an infectious disease."

and death, regardless of the shorter duration of immunity, Bridle would not acknowledge that receiving the vaccine prevented severe or serious illness and death. In fact, he stated that vaccinated people are at greater risk than unvaccinated people given his interpretation of hospital admissions.

"Respectfully, this is so far removed from the mainstream and widely accepted views of the Canadian and international medical and scientific community that the court cannot accept Dr. Bridle's evidence on the Covid vaccine as reliable," the judge ruled.

Yes, your COVID rapid tests should still work. Remember that with a lot of vaccination, symptoms will precede high viral load. You might have mild symptoms but test negative, since your immunity is keeping viral load under detection threshold. Test daily for 2-3 days to be sure.

UNIVERSITY OF GUELPH, JEFFREY WICHTEL, LAURIE ARNOTT, CHARLOTTE YATES, SCOTT WEESE, GLEN PYLE, ANDREW PEREGRINE, DOROTHEE BIENZLE, AMY GREER, DAVID FISMAN, NICK DULEY, JANE OR JOHN DOE JUNIOR SCIENTIST

Defendants

AFFIDAVIT OF DR. BONNIE MALLARD

I, Dr. Bonnie Mallard, of the City of Guelph, in the Province of Ontario, MAKE OATH AND SAY:

1. I am a professor of Immunology and Immunogenetics in the Department of Pathobiology at the University of Guelph. I have worked with Dr. Bridle since he became faculty in my department at the University of Guelph in 2012, and prior to that, when he was a student at the university. As such, I have knowledge of the matters contained in this Affidavit.

A. My Professional Background

2. I am a tenured faculty member, professor and researcher, in immunology and genetics since 1990 at the University of Guelph. I have an excellent understanding of both of those disciplines, and specifically, where the two interact. I have taught the main immunology courses, from the undergraduate to the most advanced, for over 30 years. My research focuses on genetic regulation of the immune system and implications to disease resistance.

3. My understanding of the science in the areas of mammalian immunology and genetics includes the development of vaccines. I have held and still hold a number of patents in this area.
4. I have had the distinction of receiving many awards recognizing my expertise in immunology over the course of my career, including many industry awards from what is described as "big pharma", including the Pfizer Award for Research Excellence, Zoetis Research Award in immunogenetics, and Semex Alliance.
5. I won the YMCA Lifetime Achievement Award, the University of Guelph Innovation Award and the Governor General's Award for Innovation.
6. In 2021, I won the prestigious National Sciences and Engineering Research Council of Canada, (NSERC) Synergy Prize for my work in immunogenetics. https://news.uoguelph.ca/2021/11/u-of-g-prof-wins-prestigious-award-for-innovation-in-livestock-disease-resistance/
7. I am the first and only Canadian scientist to win both the Governor General's Innovation Award and the NSERC Award and have had the honour of being recognized as one of Canada's "greatest scientists". Attached as **Exhibit A** to this affidavit is my Curriculum Vitae.

B. Expertise in Immunology required to understand vaccines

8. Vaccines have the ability to provide protection to infectious diseases because they are designed to elicit robust protective immune responses by exposing the host to non-harmful components of the infectious agent so that upon subsequent exposure to the actual pathogen, they are able to mount protective memory responses. Since vaccine development relies essentially on a sound understanding of the immune system the discipline of

vaccinology has always been within the discipline of immunology. If, for example, the vaccine is against a viral or bacterial pathogen then the expertise of virologists or bacteriologists, respectively, also plays a pivotal role. To gain the level of expertise required to develop effective vaccines generally requires training at the PhD level. The immunology training at the MD or DVM level is rudimentary and generally not sufficient to design efficacious vaccines.

C. Dr. Bridle's expertise on COVID-19 vaccines

9. Dr. Bridle has PhD training in immunology, post-doctoral training in viral immunology and, as a faculty member, developed a well-funded and respected research program in the area of viral immunology. He has worked on vaccines and cancer therapies related to various species, including humans and other mammals. Dr. Bridle holds a number of patents in this area.

10. Dr. Bridle is not a veterinarian and nor would that training be required for this work. I also am not a veterinarian, but rather hold advanced degrees in immunology and genetics. This level of knowledge and expertise of the mammalian immune system is transferable and readily qualifies for work on human and animal vaccines. In fact, vaccines are often tested in various non-human species prior to being deemed safe and effective for use in humans.

11. I have published 10 peer-reviewed research papers with Dr. Bridle that can be found on PubMed, along with various other reports, letters, and book chapters. He is an outstanding reviewer of scientific research. His scientific knowledge and the rigor of his research is remarkable, attached as **Exhibit B** is a list of my publications with Dr. Bridle. Dr. Bridle is also highly published. The impact of Dr. Bridle's peer-reviewed publications in high-quality scientific journals far exceeds that of most of our colleagues at the University of

Guelph. His publications rank in the top 5-10% of the scientific literature, in terms of their importance.

12. I am one of the long-term and the highly funded scientific researchers at the University of Guelph, having held an NSERC Discovery Grant since 1991, along with grants from numerous other agencies. Dr. Bridle's research lab ***was*** also highly successful as evidenced by his funding, training and publication record, which would be described in his resume. Dr. Bridle was also the only applicant from our department to successfully obtain funding to develop a COVID-19 vaccine.
13. In my opinion, Dr. Bridle is one of the top viral immunologists in Canada and he is highly qualified to speak with integrity and accuracy about vaccines.

D. Duty to provide expert information to members of the public

14. One of the duties of a university professor is to be able to provide their expert opinion without the fear of reprisal. Thus, tenure is earned and granted to those who are proven experts in their field so they can speak to the public about the scientific evidence related to their particular discipline. This is an important way for scientists to provide the public with information regarding their expertise.
15. It is critical that all the ideas of the experts are heard and openly discussed in various public forums to extend and advance knowledge. Transparency is important in building public confidence. This is particularly critical when the health of the public is at stake even when some of the evidence and ideas go against the government or public health narrative. At this time, when knowledge is advancing at an unprecedented rate it is acutely critical to

carefully debate the scientific knowledge and ideas in order to prevent problems when new technologies quickly emerge for public utility.

16. Therefore, it is my expert opinion that the views of all experts in the field of immunology and vaccinology should have been welcomed and openly debated and countervailing views should not have been silenced as "misinformation" either prior to, during, or after the roll out of the novel genetic vaccines against SARS-CoV-2. Dr. Fisman's opinion is that criticisms of Public Health's position on the science and vaccines against COVID-19 will undermine public confidence in taking these vaccines; however, this is a false premise since rigorous science is based on debate and consideration after viewing the relevant facts from all sides. Rarely, is there total agreement within the scientific literature. Rather transparent scientific debate and discussion are required to reach consensus. This takes time and should allow the public to see the issues from all sides. These debates are not to be personal attacks but rather to be limited to the scientific facts at hand.

17. Dr. Fisman's false, malicious-sounding, and adverse labelling of Dr. Bridle's views, a leading scientist and vaccinologist, as "disinformation", "misinformation", and then personally attacking him does nothing to safeguard any "confidence" in the public. Furthermore, not only does this damage the career of Dr. Bridle, but also the entire scientific method which relies on differing opinions, thereby eroding public trust in science itself.

18. After the COVID19 pandemic was declared, Dr. Bridle was sought out by media to provide his scientific expertise on research and science related to COVID-19 and public health policies. Dr. Bridle's media interviews and speaking engagements on COVID-19-related

issues gained popularity because he is authoritative on the topic and very articulate. The University posted Dr. Bridle's interviews on its website, attached as **Exhibit C**.

19. I co-authored several open letters with Dr. Bridle and my virology and immunology colleagues at the university. Given our collective expertise in immunology, we closely followed the scientific literature on COVID-19 vaccines and collaborated in expressing concerns about them to the public. Our letters were widely circulated, nationally and internationally. Attached as **Exhibit D** are the Open Letters co-authored by us, dated, March 3, 2021; March 5, 2021; March 11, 2021, and March 16, 2021 and March 23,2021

E. Efforts to censor and deplatform Dr. Bridle at the University

20. Dr. Scott Weese is a veterinary internist in the Department of Pathobiology at the University of Guelph. He is not a virologist or immunologist. He does not hold a PhD degree but a Doctor of Veterinary Science (DVSc), which is more clinically- than research-oriented. Dr. Weese was a member of the Ontario Science Table. Dr. Fisman was also a member of the Ontario Science Table until his resignation, which he announced on August 23, 2021.

21. On April 15, 2021, Dr. Weese criticized me and Dr. Bridle for making public statements at the monthly Pathobiology Department meeting. He told us to curtail our "messaging to the public" so they were not contrary to public health. I was shocked to hear a faculty member warn another faculty to not express views within their expertise to the public. This was a first for me in over 30 years in academia. It is common for scientists to disagree and confront one another with difference of opinions, and, to disagree with government policies, to engage in scientific inquiry.

22. Dr. Weese is also very public about his views and his media appearances are also posted by the University, thus, I was surprised by Dr. Weese's intolerance of our views and his bold attempt to censor Dr. Bridle and myself. I was also surprised and disappointed that the Dean of our department, Dr. Jeff Wichtel, shut down the conversation quickly between Dr. Bridle, Dr. Weese and myself, rather than letting the discussion go on until all points of view had been thoroughly discussed as was the norm, even though the banter was robust.
23. One of the reasons we are granted tenure as academic scientists is to inform the public without censorship, or fear of loss of career or reputation. I believe the public have the right to hear opinions presented by experts in their respective fields equally from Dr. Weese, Dr. Bridle, myself and others, regardless of, and especially if, it contradicts official, dominant government mandates. This is all the more important if the public is being asked to receive an injection with a foreign substance by the government through Public Health mandates.

F. Fisman's claims about majority of scientific opinion is false

24. Dr. Bridle's scientific opinions on COVID-19 vaccine are shared by many immunologists and virologists. He is not the only viral immunologist to have insights on COVID-19 vaccines and his views are shared by world-renowned immunologists and experts in infectious diseases.
25. **Dr. Luc Montagnier** (Nobel Laureate in virology, now deceased) expressed numerous concerns about SARS-CoV-2 and COVID-19 vaccines, for which there was overlap with issues raised by Dr. Bridle. Dr. Montagnier was among the first people to express concern that SARS-CoV-2 could be the result of gain-of-function research.[1]This concern has been

[1] https://www.livemint.com/news/world/nobel-winning-scientist-claims-covid-19-virus-was-man-made-in-wuhan-lab-11587303649821.html

openly acknowledged as a legitimate one in top-tier science journals.[2] Dr. Montagnier also shared concerns that mass rollouts of the COVID-19 vaccines had the possibility of potentiating the emergence of SARS-CoV-2 variants, and that antibody-dependent enhancement of disease could be an unwanted adverse effect of COVID-19 vaccines. Indeed, mass vaccination is known to be an efficient prophylactic strategy to protect against outbreaks, assuming a vaccine is an ideal one. However, mass vaccination is not considered to be an ideal therapeutic strategy, especially if the vaccine(s) being used are less than ideal. "Less than ideal" means being unable to prevent disease and unable to prevent transmission of the causative agent, which aptly describes the genetic COVID-19 vaccines. This is based on the well-established biological principle that applying sub-lethal selection pressures on biological entities that are prone to mutation is a classical recipe for driving the emergence of variants that can escape the pressure. This is how treatment-resistant cancers and antibiotic-resistant bacteria emerge. It is also a risk when a virus like SARS-CoV-2, which is prone to incorporating random mutations into its genome, infects hosts that fail to apply lethal immunological pressure on the virus.[3] When it came to concerns about the potential for antibody-dependent enhancement of disease, it came to light in government-issued summary documents that these same concerns were shared by the manufacturer's of the genetic COVID-19 vaccines when both Pfizer and Moderna stated, "*risk of vaccine-enhanced disease over time, potentially associated with waning immunity, remains*

unknown and needs to be evaluated further in ongoing clinical trials and in observational studies that could be conducted following authorization and/or licensure".[4]

26. **Dr. Geert Vanden Bossche** (DVM, PhD.) He held adjunct faculty appointments at universities in Belgium and Germany. Dr. Vanden Bossche joined several vaccine companies, GSK Biologicals, Novartis Vaccines, Solvay Biologicals, to serve various roles in vaccine research and development, as well as in late vaccine development. He also worked with the Bill and Melinda Gates Foundation's Global Health Discovery team in Seattle (USA) as Senior Program Officer. He also worked with the Global Alliance for Vaccines and Immunization (GAVI) in Geneva as Senior Ebola Program Manager and subsequently joined the German Center for Infection Research in Cologne as Head of the Vaccine Development Office. Like Drs. Montagnier and Bridle, Dr. Vanden Bossche shared a concern about mass vaccination during a pandemic having the potential to drive the emergence of new variants[5], although Dr. Vanden Bossche arrived at this conclusion using slightly different immunological principles than Dr. Bridle. Notably, Dr. Bridle accurately predicted that SARS-CoV-2 would become more contagious but less dangerous over time, whereas Dr. Vanden Bossche has hypothesized that the emergence of more dangerous variants is a possibility. Dr. Vanden Bossche also shares concerns that Dr. Bridle holds with respect to the importance of open debate about complex scientific problems for

[5] https://www.youtube.com/watch?v=BNyAovuUxro&t=8s

which many questions are outstanding, as well as the potential negative impact on immunological health caused by prolonged isolation of young people from the microbial world[6].

27. Numerous highly credentialed scientists that signed the Great Barrington Declaration (https://gbdeclaration.org/) also raise the same inquires and have the same insights as Dr. Bridle. That declaration has close to a million signatories showing the validity of alternative points of view to the dominant public health and government narrative on the topic of COVID-19. This would include, but is not limited to, the following:

    - **Dr. Ariel Munitz**, professor of clinical microbiology and immunology, Tel Aviv University, Israel;
    - **Dr. David Livermore**, microbiologist, infectious disease epidemiologist and professor, University of East Anglia, England;
    - **Dr. Gerhard Krönke**, physician and professor of translational immunology, University of Erlangen-Nuremberg, Germany;
    - **Dr. Motti Gerlic**, professor of clinical microbiology and immunology, Tel Aviv University, Israel;
    - **Dr. Rodney Sturdivant**, infectious disease scientist and associate professor of biostatistics, Baylor University, USA;
    - **Dr. Udi Qimron**, professor of clinical microbiology and immunology, Tel Aviv University, Israel;
    - **Dr. Ulrike Kämmerer**, professor and expert in virology, immunology and cell biology, University of Würzburg, Germany;

[6] https://sciencebasedmedicine.org/countering-geert-vanden-bossches-dubious-viral-open-letter-warning-against-mass-covid-19-vaccination/

- **Dr. Sunetra Gupta,** professor at Oxford University, an epidemiologist with expertise in immunology, vaccine development, and mathematical modeling of infectious diseases.

28. There is also an extensive list of scientists from around the whole that are part of the World Council for Health that share similar views to Dr. Bridle because of their expertise (https://worldcouncilforhealth.org/), including Dr. Tess Lawrie, the director of the Evidence-based Medicine Consultancy in Bath, UK.

29. The point here is that alternative views to government public health mandates are shared by thousands of researchers, physicians and scientists from all disciplines, so there is no need to try to silence or ostracize Dr. Bridle by claiming he is "spreading misinformation" for expressing scientific opinions in his field of expertise. It is far better to encourage the debate and let the best ideas float to the top rather than being dictated in a top-down fashion on the pretext that contradicting public health is "dangerous" or with unspecified and unsubstantiated claims of "public harm".

30. Such irresponsible and high-handed claims being made by a medical doctor and an academic, such as Dr. Fisman, cause ostracization and censorship. It sends a message to other scientists to not express their countervailing views. This is what happened to Dr. Bridle because of Dr. Fisman's allegations of misinformation against Dr. Bridle, which occurred in late May 2021. Since then, Dr. Bridle's public speaking engagements and media interviews regarding his expertise in COVID-19 vaccines were not announced, or posted, by the University https://www.uoguelph.ca/research/covid-research-stories/ovc.

G. Dr. Bridle's scientific predictions were accurate and not "misinformation"

31. I have read the affidavit of Dr. David Fisman filed in this motion. His claims that Dr. Bridle's opinions regarding COVID-19 vaccines are:

    a. "not scientifically sound";

    b. "implausible";

    c. "not evidence based" and "not data-based",

    d. Or that Dr. Bridle "posed a risk to the public";

    e. and is "spreading misinformation". These are all false and unjustified.

32. As a senior immunologist, I can confirm that Dr. Bridle's public communication on COVID-19 vaccines was, and is, not only based on scientific evidence and data, but his insights and predictions proved to be true and accurate, and are beneficial for public health because open discussion and criticism by experts inform better public policy decision making.

33. Dr. Fisman's allegations are unjustified and improper because for more than one year since the declaration of the pandemic in March 2020, Dr. Bridle accurately identified issues with COVID-19 vaccines, which were later admitted by government.

34. On August 17, 2020, at the *COVID-19 Science and Policy Symposium*, Dr. Bridle raised concerns about blood clots related to the Health Canada-authorized AstraZeneca COVID-19 vaccine. His presentation is available here: https://www.youtube.com/watch?v=HndetYzK8gU. Seven months later, on March 29, 2021, Health Canada discontinued its use for ages 55 and under, for concerns over blood clots: https://www.canada.ca/en/public-health/news/2021/03/use-of-astrazeneca-covid-19-vaccine.html

35. On February 10, 2021, Dr. Bridle published an article in The Conversation, in which he discussed the duration of immunity, where, if protection conferred by the vaccination did not have a sufficient duration, that the populations who were vaccinated first would lose their immunity while other populations were still being vaccinated, and therefore there would be insufficient immunity, leading to the virus spreading again through the initially vaccinated people.[8] These concerns are true, as the COVID-19 vaccines are now understood to start losing their effectiveness within one month and they become ineffective within only six months[9].

36. On June 15, 2020, in another article published in The Conversation, Dr. Bridle expressed concerns about the short research timelines in the development of the COVID-19 vaccines[10]. On March 24, 2021, Dr. Bridle expressed concern about lack of data on long-term adverse effects and efficacy. On November 16, 2023, Health Canada acknowledged that efficacy and potential long-term adverse effects of the COVID-19 vaccines were unknown at the time of the public rollout.[11]

---

[8] https://theconversation.com/5-factors-that-could-dictate-the-success-or-failure-of-the-covid-19-vaccine-rollout-152856

[9] Addo IY, Dadzie FA, Okeke SR, Boadi C, Boadu EF. Duration of immunity following full vaccination against SARS-CoV-2: a systematic review. Arch Public Health. 2022 Sep 2;80(1):200. doi: 10.1186/s13690-022-00935-x. PMID: 36050781; PMCID: PMC9436729.

[10] https://theconversation.com/fast-covid-19-vaccine-timelines-are-unrealistic-and-put-the-integrity-of-scientists-at-risk-139824

[11] It should be noted that in the original purchase agreement between Pfizer and the Minister of Public Works and Government Services dated October 26, 2020, in Section 5.5 "Purchaser Acknowledgement" (page 18), the Government of Canada acknowledged that "the long-term effects and efficacy of the Vaccine are not currently known and there may be adverse effects of the Vaccine that are not currently known. Further, to the extent applicable, Purchaser acknowledges that the Product shall not be serialized." [(2020) Manufacturing and supply agreement between Pfizer Canada ULC and her Majesty the Queen in Right of Canada, represented by the Minister of Public Works and Government Services Canada dated October 26, 2020. X. Retrieved from https://twitter.com/canindependent/status/1724438683963515231]
In other words, Health Canada would not be able to track any particular Pfizer COVID-19 vaccine batches for efficacy and safety. By the beginning of December 2020, the Canadian government had 154 million COVID-19 vaccines doses for its 38 million population, which works out to 4 doses for every person in Canada. [Rastello, S., Bolongaro, K. (2020) Canada has reserved more vaccine doses per person than anywhere. BNN Bloomberg News. Retrieved

37. On May 27, 2021, Dr. Bridle was interviewed on the program "ON Point" with Alex Pierson on Global[12]. All Dr. Bridle's claims are now accepted principles in the peer-reviewed scientific literature. Specifically, Dr. Bridle stated there could potentially be a link between the mRNA vaccines and cases of myocarditis that were being diagnosed in young males shortly after immunization. He also stated that a preclinical study submitted to the Japanese health regulatory agency showed that the lipid nanoparticles used to deliver mRNAs in Pfizer's COVID-19 vaccine got widely distributed throughout the body, which agreed with the long historical understanding of this technology but contradicted public health messaging about the vaccines remaining at the injection site. With respect to concerning data showing the lipid nanoparticles accumulating in the ovaries, Dr. Bridle questioned whether this could have any impact on fertility. This was clearly posed as a scientific question, not a statement of fact. Finally, Dr. Bridle expressed concerns, based on his assessment of pathogenesis studies of natural infections with SARS-CoV-2, that the spike protein was a bioactive molecule that had the potential to cause harm in the body (*i.e.*, have toxic effects) if it got systemically distributed.

H. Dr. Fisman's claims are irresponsible, unjustified and malicious

38. On May 30 and 31st, 2021, I was forwared and copied on emails from Dr. Bridle attaching posts on Twitter by Dr. Fisman and Dr. Glen Pyle, and Weese, attached as **Exhibit E.**

---

from https://www.bnnbloomberg.ca/canada-has-reserved-more-vaccine-doses-per-person-than-anywhere-1.1533041] In short, Health Canada could not, with any degree of certainty, comment on safety and efficacy of this Pfizer product.

3. The Alex Pierson Show: New peer reviewed study on COVID-19 vaccines suggests why heart inflammation, blood clots and other dangerous side effects occur on Apple Podcasts [hereinafter "On Point interview"]

39. Dr. Fisman's post dated May 29th, 2021 reads:

> "I've had questions over the past 48h about vaccine safety concerns aired Dr Bryam Bridle at @UofGuelphOAC in some recent interviews. I don't know Dr Bridle but he's a legit immunologist. Some claims, however, are not data based, and are answered here: byrambridle.com"

40. Dr. Fisman does not identify any claims which are not "data based" in his May 29th, 2021, post for the public to understand what exactly constituted "misinformation". It is unfair to allege an expert is making false claims without specifying what those are. It is also unjustified and high-handed for Dr. Fisman to claim that Dr. Bridle's answers are "not data-based". As an academic and scientist, he owed Dr. Bridle the courtesy of notifying him, and members of the public, about *which* claims were not data-based and an opportunity for Dr. Bridle to respond. In fact, Dr. Bridle stated in his interview with Alex Pierson that he was in the process of assembling the scientific basis for his concerns. So, Dr. Fisman should have known that Dr. Bridle had data that could be shared. After all, it is not possible to 'show data' in the context of a radio interview intended for a lay audience. Dr. Bridle followed through on this by publishing "COVID-19 vaccines and Children: A Scientist's Guide for Parents" is attached as "**Exhibit F**", along with two briefing documents which Dr. Fisman never referenced.

41. Dr. Fisman directs the public to a website which he states provides responses to the unidentified claims "***from Dr. Bridle's colleagues***"[15]. First, referring the public to a website he knows is not authorised by Dr. Bridle, and was set up to impersonate him, is malicious. Second, Dr. Pyle has denied any connection with the website that impersonates him.

---

[15] Affidavit of Dr. Fisman at paragraph 21.

42. In his email to *USA Today* reporter Daniel Funke, Dr. Fisman states Dr. Bridle relied on an "odd document" during the ON Point interview[16]. Dr. Bridle based his comments on the Pfizer biodistribution study of where lipid nanoparticles go in the body. It is not an "odd document", as asserted by Dr. Fisman[17]. It is a scientific study that was conducted by Acuitas Therapeutics Inc. which is attached as "**Exhibit G**". The Acuitas study was confirmed by a study conducted by Pfizer and submitted to the Japanese Health regulatory agency. It was made publicly available via their website. Tables on page 6 and 7 are in English. Tables and figures should stand alone and a good scientist should be able to read and interpret the tables without reading the text. Attached as "**Exhibit H**", is a copy of the Japanese study. Subsequently, a court in the United States compelled the Food and Drug Administration to publicly release their version of the study. Dr. Fisman's referral to it as an "odd" document to an international journalist, is deceptive, shows a lack of understanding of the health regulatory process, and only acts as a smear.[18]

43. Dr. Fisman's only reason for objecting to Dr. Bridle's public comments seems to be that he was ***contradicting*** public health messaging. However, that in itself is not grounds for an accusation of misinformation.

44. The post by Dr. Fisman dated May 30, 2021, reads:

> "An excellent follow for good ***immune science from @UofGuelphOAC*** is Dr. @glenplye, who has addressed some of the misinformation in these interviews on his own tweets" (emphasis added)

45. I am one of Dr. Bridle's ***immunology*** colleagues. I was not contacted by Dr. Fisman to respond to concerns about claims which may be "misinformation". There are other

[16] Affidavit of Dr. Fisman at paragraph 30, Exhibit "N", page 184
[17] Ibid
[18] Affidavit of Dr. Fisman, Defendants Motion Record, page 183

immunologists at the University of Guelph or elsewhere, Dr. Fisman could have referred the public to for "good immune science". Dr. Pyle is neither an immunologist nor a virologist; he is however one of the faculty members seeking to censor and smear Dr. Bridle at our university. Dr. Fisman's referral to Dr. Pyle for "good immune science" on COVID-19 vaccines is disingenuous.

46. Dr. Fisman's subsequent Twitter post, again refers the public to and promotes the website impersonating Dr. Bridle:

> "The website debunking Dr. Bridle's covid-19 vaccine claims has been updated with lots of peer-reviewed science that attests to the safety of vaccines.
>
> Byrambridle.com
>
> And for those who think I made or organized this website: nope. But grateful to the scientists who did."

47. On February 22, 2021, I was interviewed by a detective in the Fraud Bureau of Municipal Regional Police Service. I was advised by the detective and do verily believe that the website is being investigated for "criminal harassment" and "identity fraud"[19].

48. The website is not a credible or knowledgeable source for scientific resource. It is improper and unethical for Dr. Fisman, a medical doctor, and tenured professor, to repeatedly direct members of the public to a website that impersonates a viral immunologist and an academic colleague with the intent to defame and discredit him.

49. Dr. Fisman's reference to Dr. Pyle from June 17th, to June 23rd, 2021 and his messages intertwining with Dr. Weese do not constitute scientific discussion. On June 23, 2021, I received an email from a research associate at the University of Guelph (who fears reprisal

[19] sections 403.1 & s.264(2)(b) of the Criminal Code

from Weese and Pyle) with screenshots of Twitter posts by Dr. Weese and Dr. Pyle in response to Dr. Bridle's research report titled "COVID-19 vaccines and Children: A Scientist's Guide for Parents" Dr. Weese posted a picture of a farmer shovelling manure, and another post, in response to a press conference on Parliament Hill, he called Dr. Bridle an "anti-vaxxer", attached as **Exhibit I.**

50. It became apparent to me that Dr. Bridle, was referred to as an "anti-vaxxer" and disseminator of "misinformation", to tarnish his stellar reputation as a vaccinologist, and discredit him so that the public would not listen to his expert opinion. The allegations otherwise are nonsensical because Dr. Bridle is a career vaccinologist who develops and researches vaccine. It is absurd and irrational to allege that a viral immunologist with a speciality in vaccinology and multiple patent holder for vaccines is "anti vax".

51. I another post Dr. Fisman's combined social media posts, with Dr. Weese, re-tweeting an old Tweet from Dr. Fisman, dated May 10, 2021, links "anti-vaxxers" to "neo-Nazi white supremacist" with a link that goes directly to Dr. Bridle's picture, name and place of work. Dr. Weese makes a link between Dr. Bridle, lies, white supremacist and neo-Nazis through Dr. Fisman's posts. There is no discussion of science and Dr. Fisman does nothing to denounce the reckless and vindictive re-posting of his tweet.

I. University's complicity in smear campaign and online harassment against Dr. Bridle

52. On June 7, 2021, July 7, 2021, and September 9, 2021, I emailed the Dean of our department, Dr. Jeff Wichtel, and others, with concerns, regarding the combined Tweets of Drs. Fisman, Pyle and Weese attached as **Exhibit J**:

"I wanted to let you know that I find it very disappointing that after Byram's interview last week the "Fact Checkers" and others on social media etc called this false news when in fact he reported on two important findings: 1 - the Pfizer report to the Japanese government (linked below, see tables on page 6-7) showing that their LNP formulation carrying mRNA is distributed within 15 minutes to most organs and tissues and remains for at least 48 hours. This bio-distribution study was done in rats which is appropriate and another study in primates showed similar results.

In addition, he spoke about an accepted peer reviewed paper by Ogata et al (authors from U of Montreal and Harvard, linked below) that showed the presence of viral spike protein in the circulation of 11 out of 12 health care workers following immunization with the mRNA 1273 vaccine. This substantiates the idea that the mRNA is being translated into spike protein in large enough quantities and finding its way from the local site/draining nodes into the circulation where it can bind to platelets and endothelial cells potentially causing damage.

This is in no way false information. In fact, it is right here in black and white along with a large number of other reports and manuscripts (I attached just a smattering) describing various concerns associated with these nucleic acid vaccines, particularly for use in children.

Why is it all of a sudden a crime or false news when a group of credible scientists offer up their valid concerns to the public, particularly about vaccinating children?

It is inappropriate in my view to let Byram be slandered by all types of false claims and say nothing. I hope you can offer some suggestions to support our colleague."

53. My email dated September 9, 2021, states, in part:

"Scott has been tweeting slanderous comments against Byram for months now and nothing has been done to stop it.
Meanwhile, Byram is the one being accused of harassment. I think the shoe is on the wrong foot here.
In my 30 years as faculty I have never seen such nonsense. To call Byram an anti-Vaxxer is completely ridiculous since his entire career revolves around vaccine production. Showing a picture of a person shovelling manure and implying this is Byram is beyond belief.
Since when do we not accept other faculty with alternative points of view rather than slandering them on social media."

54. Dean Witchel suggested that Dr. Bridle "withdraw from social media discourse", completely failing to appreciate that Dr. Bridle was not on Twitter and had no social media presence whatsoever; the attacks were one-sided.

55. On July 6, 2021, two faculty members that Dr. Fisman posted messages with on Twitter, Drs. Pyle and Weese, wrote a letter with Drs. Greer and Bienzle repeating Dr. Fisman's allegations against Dr. Bridle for "spreading misinformation" on COVID-19 vaccines, attached as **Exhibit K**.

56. As a senior viral immunologist and as a researcher and developer of vaccines, including COVID-19 vaccines, Dr. Bridle is a strong proponent of using high quality vaccines in a correct and evidence-based manner. The letter was singularly directed at Dr. Bridle and personalized to attack him. If the letter had been about the issues raised by the scientific debate on COVID-19 vaccines it would have been addressed to and involved all the senior immunologists on campus, that would have been fair comment as several of us hold the exact same views as Dr. Bridle.

57. On July 7, 2023, I wrote to the university again. Dean Witchel, replied that the university would not "referee scientific discourse in the media", which missed the point again that Dr. Bridle was not part of the Twitter discourse, but subject to one-sided attacks, and the content was not about science but vicious name-calling.

58. On July 14, 2021, I co-authored a letter in support of Dr. Bridle to address the science in the July 6, 2021, letter and unlike the letter written by Drs. Weese, Pyle, Bienzle and Greer, I did not mention any names. The letter is science-based and not a personal letter against anyone. Attached as **Exhibit L.**

J. Harms for alleging Dr. Bridle is "an immunologist spreading misinformation"

59. Dr. Bridle has conducted research and development of vaccines at the University of Guelph for over a decade. He took the time and effort to carefully develop a well-funded research program around his areas of expertise in immunology, vaccinology and cancer biology. His funding and publication record grew steadily over time. He has received various teaching and research awards. He was granted tenure as a university professor which acknowledges his expertise on a national and international level. As someone who was one of his mentors, there is no doubt that Dr. Bridle was on an upward career trajectory as a world class scientist. Dr. Bridle's vaccine development research is dependent on funding from third party donors/grantors.

60. Dr. Bridle being labelled as "spreading misinformation" by Dr. Fisman, in conjunction with Drs. Pyle and Weese, has incredibly harmed his research and reputation as a scientist. The false web-site erected under his name has cast doubt on his credibility and caused a great deal of confusion.

61. When a scientist is accused of publishing, presenting or "spreading" "misinformation" or "disinformation" it is taken by others in the scientific community to mean a fraudulent resuscitation of science which amounts to the "kiss of death" for the scientist accused, even where the accusation is false.

62. I pointed this out in my letter to Dean of our Department on June 7, 2021:

> "Byram has always been a respected and successful member of our faculty, and I am saddened to see people go after him in such a malicious manner on social media including members of our own faculty. Some have now even removed him from their grant applications. These types of slanderous posts can have a negative impact on his career and should be actively discouraged. As you point out, there is a scientific process to follow and Byram would be happy to discuss these papers with any interested parties. However, he has not been given that opportunity by the people posting against him for no valid reason."

63. Dr. Bridle has limited resources left to support his staff, students, or research. It will take him years to rebuild his research program and team of experts, as well as to reclaim his reputation. His research program required approximately $500,000 dollars to get up and running and approximately $250,000 per year in ongoing operating costs. It takes a minimum of five years to get a research program running and fully functional and to demonstrate a track-record of success that is needed to garner funding from conventional sources. This means that Dr. Bridle will require at least $1,250,000 to re-establish his program.

64. There has also been a negative impact on students and staff hearing the disparaging and insulting social media posts about Dr. Bridle. In fact, one of my own research associates was so dishearten by these posts and the situation within our department that she asked not to come into work on at least one occasion. The junior scientists on my team also expressed their concerns about the vaccines and the treatment of Dr. Bridle but didn't want to say anything for fear of harm against their future at the university or as budding immunologists. We actually put together a support group for some of the students on campus that didn't want to take the vaccine and wanted to hear what Dr Bridle had to say. They could see the evidence was rapidly going in his favour (*e.g.*, risk of myocarditis, particularly in young males).

65. These harms and attempts to silence experts, such as Dr. Bridle, has also had a chilling effect on me. It became clear very early on that to provide an opposing point of view even when backed up by the scientific evidence was going to cause alienation from my colleagues. Previously, opposing points of view were encouraged and valued to help sharpen the thinking on any given issue, but this was not the case when it came to COVID-

19 and the associated vaccinations. No one wanted to discuss the issues, even proof of naturally-acquired immunity to SARS-CoV-2 was not valued, and once those that were not vaccinated were not allowed in the building, the alienation and silencing of opposing voices was complete. Also, as a result of the smear campaign and vicious social media attacks on Dr. Bridle's character and credentials I am very cautious of Drs. Pyle and Weese. I saw the damage that they can do a colleague's career.

Guelph Women of Distinction: Education, Training and Mentorship
YMCA Guelph
Distinction
Women of Distinction is an annual fundraiser held by the YMCA - YWCA of Guelph to recognize and celebrate the achievements of women in City of Guelph and Wellington County. The fundraiser supports programs run by the YMCA - YWCA of Guelph for women, teens, and their families. Women of Distinction supports Guelph Y programs for girls and women at all stages of life in Guelph and Wellington County, including: Power of Being a Girl - A one day conference for girls that helps build self-esteem and raises awareness about healthy relationships Teenage Parents Program (TAPPs) - A program that supports the personal growth and development of pregnant and parenting teens and their families and connects them with valuable resources Encore - A holistic program for women with breast cancer to help them build their own physical strength, as well as feel the strength and support of a community

2018/3	Guelph Women of Distinction: Lifetime Achievement Award YMCA Distinction Honoured for her groundbreaking High Immune Response technology used to breed healthier cattle, as well as for being a mentor and for co-founding the Sunrise Therapeutic Riding and Learning Centre in Puslinch, Ontario
2017/7	University of Guelph Innovation of the Year Award Catalyst Centre: Research Innovation Office UofG Prize / Award The Innovation of the Year Award has been developed to recognize and celebrate Guelph innovations that have made, or have the potential to make, significant socioeconomic impacts to Canada and beyond.
2017/5	Governor General's Innovation Award for Advancements in Immunogenetics Canada Foundation for Innovation Prize / Award In today's competitive and interconnected world, increasing productivity through the creation of new products and services, improving public sector performance, and building an inclusive, compassionate society will be the keys to Canada's success as a caring, efficient and prosperous nation. The purpose, therefore, of the Governor General's Innovation Awards is to inspire Canadians to embrace innovation and to emulate innovative, entrepreneurial risk-takers who have developed new or better ways of creating value and who are having a meaningful impact on our quality of life. As innovation and an entrepreneurial spirit are fundamentally important to all Canadians and can have a transformative, positive impact—regardless of whether it is in the private, public or not-for-profit realms—the awards encompass all sectors of Canadian society.

User Profile

Research Specialization Keywords: immunology, genetics, genomics, infectious disease, health, disease prevention

Employment

2000/6	Professor of Immunogenetics Pathobiology, University of Guelph Full-time, Professor Tenure Status: Tenure Research and Teaching Professor
2005/1 - 2010/1	Professor of Immunogenetics Biology, Science, University of Sherbrooke Part-time, Adjunct Tenure Status: Non Tenure Track
1993/11 - 2000/5	Professor of Immunogenetics Pathobiology, Ontario Veterinary College, University of Guelph Full-time, Associate Professor Tenure Status: Tenure Research and Teaching Professor
1990/1 - 1993/11	Professor of Immunogenetics Veterinary Immunology and Microbiology, Ontario Veterinary College, University of Guelph Full-time, Assistant Professor Tenure Status: Tenure Track Research and Teaching Professor

Research Funding History

Awarded [n=14]

2022/4 - 2027/3
Principal Applicant

Improving Livestock for Climate Resilience, Grant

Funding Sources:
Canada First Research Excellence Fund
Food from Thought
Total Funding ~300,000
Portion of Funding Received - 181,390
Funding Competitive?: Yes

2020/1 - 2028/1
Principal Investigator

Synergy Prize for Innovation, Grant

Funding Sources:
Natural Sciences and Engineering Research Council of Canada (NSERC)
Synergy Prize
Total Funding - 400,000
Portion of Funding Received - 200,000
Funding Competitive?: Yes

2018/10 - 2022/12
Co-applicant

Translating High Immune Response (HIR™) Genomics to Improve Beef Cattle Health and Welfare, Grant

Funding Sources:
Genome Canada
Genomic Applied Partnerships Program
Total Funding - 1,617,164
Portion of Funding Received - 800,476
Funding Competitive?: Yes

2020/5 - 2023/12
Principal Applicant

Immunity+ Colostrum: Building a State-of-the-Art Colostrum Product for Better Calf Health, Grant

Funding Sources:
Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA)
Gryphon's LAAIR (Leading to the Accelerated Adoption of Innovative Research)
Total Funding - 106,000
Portion of Funding Received - 106,000
Funding Competitive?: Yes

2018/10 - 2022/12
Principal Applicant

Evaluation of the High Immune Response Technology™ in beef cattle in the context of climate change, calf health and the development of a genomics test for immune response, Grant

Funding Sources:
Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA)
University of Guelph - OMAFRA Research Theme: Tier II
Total Funding - 48,571
Portion of Funding Received - 48,571
Funding Competitive?: Yes

2018/10 - 2022/10
Decision Maker

Translation of the HIR technology for use in beef cattle, Scholarship

Funding Sources:
Mitacs
Accelerate
Total Funding - 80,000
Portion of Funding Received - 80,000

Funding Competitive?: Yes

2021/5 - 2023/8
Principal Investigator

Maintaining Immunity+ Colostrum Bioactivity using a Unique Cold Plasma Method, Grant

Funding Sources:
Canada First Research Excellence Fund
Food from Thought - Commercialization Grant Program
Total Funding - 50,000
Portion of Funding Received - 50,000
Funding Competitive?: Yes
Semex Canada
Total Funding - 10,000
Portion of Funding Received - 10,000
Funding Competitive?: No

Co-investigator : Art Hill; Kevin Keener

2017/4 - 2022/3
Principal Applicant

Mechanisms and Genes that Shape Bovine Host Defense, Grant

Funding Sources:
Natural Sciences and Engineering Research Council of Canada (NSERC)
Discovery
Total Funding - 201,000
Portion of Funding Received - 201,000
Funding Competitive?: Yes

2020/7 - 2021/6
Co-applicant

Application of Genomics-based Methods to Select for Pig Disease Resilience, Grant

Funding Sources:
Genome Canada
Genomic Applied Partnerships Program
Total Funding - 1,026,200
Portion of Funding Received - 135,400
Funding Competitive?: Yes

2016/9 - 2021/1
Decision Maker

Canada First Research Excellence Fund - Food from Thought, Grant

Funding Sources:
Canada First Reserach Excellence Fund
Food from Thought
Total Funding - 7,660,000
Portion of Funding Received - 350,000
Funding Competitive?: Yes

Decision Maker : Bonnie Mallard; Clarence Swanton; Evan Fraser; Jan Sargeant; Jeffrey Farber; Kari Dunfield; Kevin McCann; Malcolm Campbell; Paul Hebert; Tina Widowski

2018/8 - 2024/8
Co-investigator

Use of the High Immune Response technology to access bovine immune responsivenss, Contract

Funding Sources:
The Semex Alliance Inc
Total Funding - ~955,248
Portion of Funding Received - ~815,453
Funding Competitive?: No

2019/7 - 2020/7
Co-investigator

Telemetry equipment to monitor body temperature, respiratory and heart rate in dairy cattle and other animals, Grant

Funding Sources:
University of Guelph
Research Tools and Instruments Grant Program

Total Funding - 165,000
Portion of Funding Received - 165,000
Funding Competitive?: Yes

2019/1 - 2020/1
Principal Applicant

Examining MHC Polymorphism in Holstein Dairy Sires, Grant

Funding Sources:
The Semex Alliance Inc
Total Funding - 25,000
Portion of Funding Received - 25,000
Funding Competitive?: No

2018/1 - 2020/1
Principal Applicant

Investigating the Health and Economic Benefits of Colostrum and Milk from Dairy Cattle Selected for Enhanced Immunity, Grant

Funding Sources:
The Semex Alliance Inc
Collaborative Research and Development Grant
Total Funding - 422,157
Portion of Funding Received - 422,157
Funding Competitive?: Yes
Natural Sciences and Engineering Research Council of Canada (NSERC)
Collaborative Research and Development Grant
Total Funding - 422,157
Portion of Funding Received - 188,390
Funding Competitive?: Yes

Completed [n=10]

2017/2 - 2019/1
Collaborator

Mitacs Elevate Fellowship awarded to Dr. Lauri Wagter-Lesperance in partnership with Dr. Bonnie Mallard and the Semex Alliance Inc., Fellowship

Funding Sources:
Semex Alliance Canada
Mitacs Elevate
Total Funding - 60,000
Portion of Funding Received - 60,000
Funding Competitive?: Yes

2016/6 - 2018/10
Co-applicant

Animal Models to Select for Disease Resilience: High Immune Response Technology in Swine, Grant

Funding Sources:
Ontario Research Fund (ORF)
Strategic Value Review
Total Funding - 250,000
Portion of Funding Received - 250,000
Funding Competitive?: Yes

2015/10 - 2018/10
Co-applicant

Application of Genomics to Improve Disease Resilience and Sustainability in Pork Production, Grant

Funding Sources:
Genome Canada
Large Scale Applied Research Program: Genomics and Feeding the Future
Total Funding - 9,983,836
Portion of Funding Received - 116,263
Funding Competitive?: Yes

2016/8 - 2018/8 Principal Applicant	Use of the High Immune Response technology to access bovine immune responsivenss, Contract **Funding Sources:** The Semex Alliance Inc Total Funding - 256,000 Portion of Funding Received - 256,000 Funding Competitive?: No
2015/6 - 2018/7 Principal Applicant	Genetic Selection for Disease Resistance: Adapting Immunity+ /High Immune Response (HIR) Technology for Application in the Beef Industry, Grant **Funding Sources:** Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA) Gryphon's LAAIR: Leading to Accelerated Adoption of Innovative Research Total Funding - 124,794 Portion of Funding Received - 124,794 Funding Competitive?: Yes
2016/5 - 2017/4 Principal Applicant	Investigating Mechanisms and Genes that Shape Bovine Host Defense and affect Disease Outcome in High and Low Immune Responder Phenotypes, Grant **Funding Sources:** NSERC Discovery Total Funding - 29,000 Portion of Funding Received - 29,000 Funding Competitive?: Yes
2014/1 - 2017/1 Principal Applicant	Genetic and Genomic Approaches to Improve Dairy Health, Food Quality and Farm Profitability through Enhanced Immune Response, Grant **Funding Sources:** Boviteq Inc. Total Funding - 420,200 Portion of Funding Received - 420,200 Funding Competitive?: Yes Natural Sciences and Engineering Research Council of Canada (NSERC) Total Funding - 419,000 Portion of Funding Received - 419,000 Funding Competitive?: Yes
2014/9 - 2016/9 Co-investigator	Assessing the bioactivity of immune-related microRNAs in colostrum and milk from high and low immune responder cows on human intestinal epithelial cells, Grant **Funding Sources:** Dairy Farmers of Ontario Total Funding - 112,500 Portion of Funding Received - 112,500 Funding Competitive?: Yes Natural Sciences and Engineering Research Council of Canada (NSERC) Total Funding - 112,500 Portion of Funding Received - 112,500 Funding Competitive?: Yes Principal Applicant : Niel Karrow
2013/8 - 2016/8 Principal Applicant	Transferring the High Immune Response technology to industry for testing bovine sires, Contract **Funding Sources:**

The Semex Alliance Inc
Total Funding - 384,000
Portion of Funding Received - 384,000
Funding Competitive?: No

2014/5 - 2016/5
Principal Applicant

Assessing the bioactivity of immune-related microRNA in colostrum and milk from high and low immune responder cows on intestinal epithelial cells, Grant

Funding Sources:
Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA)
Total Funding - 175,000
Portion of Funding Received - 175,000
Funding Competitive?: Yes

Student/Postdoctoral Supervision

Bachelor's [n=17]

2022/5 - 2022/8
Principal Supervisor

Yuqi Liang (In Progress) , University of Guelph
Thesis/Project Title: Immunity+ colostrum
Present Position: undergraduate student

2022/5 - 2022/8
Co-Supervisor

Sophie Tieu (In Progress) , University of Guelph
Thesis/Project Title: Vitamin D as an immunoceutical
Present Position: veterinary student

2021/5 - 2021/8
Principal Supervisor

Marijke Boerefyn (Completed) , University of Guelph
Thesis/Project Title: Benchmarking genetic influences on disease survivability and colostrum quality in dairy calves
Present Position: gradulate student

2021/5 - 2021/8
Principal Supervisor

Laura Willis (Completed) , University of Guelph
Thesis/Project Title: Bioactivity of colostrum after various processing methods
Present Position: veterinary student, University of Guelph

2020/5 - 2020/8
Academic Advisor

Samantha Streekstra (Completed) , University of Guelph
Thesis/Project Title: Investigation of Colostrum Quality of HIR Dairy Cattle
Present Position: Nurse, McMaster University

2020/5 - 2020/8
Academic Advisor

Connor Bryant (Completed) , University of Guelph
Thesis/Project Title: Investigation of Colostrum quality from HIR Dairy Cattle
Present Position: veterinarian, Ontario Veterinary College

2020/5 - 2020/8
Academic Advisor

Matthew Vermey (Completed) , University of Guelph
Thesis/Project Title: Translating the HIR Technology for use in Angus Beef Cattle
Present Position: Veterinary Medicine Student, Ontario Veterinary College

2019/5 - 2020/5
Principal Supervisor

Samantha Streekstra (Completed) , University of Guelph
Thesis/Project Title: Immunogenetics
Present Position: unknown

2019/5 - 2019/8
Principal Supervisor

Connor Bryant (Completed) , University of Guelph
Thesis/Project Title: immunogenetics
Present Position: Veterinary medicine student, Ontario Veterinary College

2019/5 - 2019/8
Principal Supervisor

Royan Pariappadan (Completed) , University of Guelph
Thesis/Project Title: Immunogenetics
Present Position: Medical Student

2019/5 - 2019/8 Principal Supervisor	Siobhan Mellors (Completed) , University of Guelph Thesis/Project Title: Immunogenetics Present Position: unknown
2017/5 - 2018/4 Principal Supervisor	Kiersten Hanada (Completed) , University of Guelph Thesis/Project Title: MicroRNA in bovine colostrum and milk Present Position: veterinarian
2017/5 - 2018/12 Principal Supervisor	Gabriel Laplante (Completed) , University of Guelph Thesis/Project Title: Immunogenetics Present Position: unknown
2017/5 - 2017/8 Principal Supervisor	Christine Barnes (Completed) , University of Guelph Thesis/Project Title: Assessment of HIR Technology for use in beef cattle and thoroughbred horses. Present Position: veterinarian
2016/5 - 2016/8 Principal Supervisor	Elfleda Chik (Completed) , University of Guelph Thesis/Project Title: Assessment of HIR Technology in Beef Cattle Present Position: veterinarian
2016/5 - 2017/8 Principal Supervisor	Keeley Burnside (Completed) , University of Western Ontario Thesis/Project Title: MicroRNA in bovine colostrum and milk Present Position: Physiotherapist
2016/5 - 2016/8 Principal Supervisor	Christine Barnes (Completed) , University of Guelph Thesis/Project Title: Assessment of HIR Technology for use in beef cattle and thoroughbred horses. Present Position: veterinarian

Bachelor's Equivalent [n=1]

2016/5 - 2016/12 Principal Supervisor	Nasrin Satayesh Husseini (Completed) , University of Guelph Thesis/Project Title: Assessment of HIR Technology for beef cattle Present Position: Agriculturalist

Master's non-Thesis [n=1]

2017/1 - 2017/9 Co-Supervisor	Alexandra Livernois (Completed) , University of Guelph Thesis/Project Title: Bioinformatics Present Position: Scientist

Master's Thesis [n=4]

2017/5 - 2020/8 Principal Supervisor	Nasrin Satayesh Husseini (Completed) , University of Guelph Thesis/Project Title: Assessment of the HIR Technology for beef cattle Present Position: Research Technician
2014/9 - 2017/9 Principal Supervisor	Mikayla Ross (Completed) , University of Guelph Thesis/Project Title: Assessing the bioactivity of immune-related microRNA in colostrum and milk from high and low immune responder cows Present Position: industry researcher
2014/9 - 2016/12 Academic Advisor	Adrianna Laursen (Completed) , University of Guelph Thesis/Project Title: The role of gamma-delta T-cells in immunity to Marek's Disease Present Position: unknown
2013/4 - 2016/1 Academic Advisor	Alicia Coyne (Completed) , University of Guelph Thesis/Project Title: Lactoferrin in milk of Holstein dairy cows. Present Position: unknown

Doctorate [n=10]

2018/9 - 2022/9 Principal Supervisor	Tess Altvater-Hughes (In Progress) , University of Guelph Thesis/Project Title: HIR/Immunity+ Colostrum Present Position: gradulate student
2018/9 - 2022/9 Principal Supervisor	Shannon Beard (In Progress) , Univeristy of Guelph Thesis/Project Title: HIR/Immunity+ Genomics for Angus beef Present Position: gradulate student
2017/9 - 2022/9 Principal Supervisor	Shannon Cartwright (In Progress) , University of Guelph Thesis/Project Title: Impact of Climate Variability on the Resilience of Dairy Cattle Classified as High, Average or Low Immune Responders Present Position: gradulate student
2014/9 - 2018/8 Academic Advisor	Kevin Stinton (Completed) , University of Guelph Thesis/Project Title: Immune response to Johne's Disease in cattle. Present Position: researcher
2014/9 - 2019/11 Principal Supervisor	Mehdi Emam (Completed) , University of Guelph Thesis/Project Title: Cellular Immuno-Genomics: A Systems Biology Approach to Investigate Genetic Regulation of Macrophage Function and Disease Resistance of Dairy Cattle Present Position: Post-doctoral Fellow, McGill
2014/9 - 2017/1 Academic Advisor	Alison Fleming (Completed) , University of Guelph Thesis/Project Title: Milk spectral analysis. Present Position: industry
2013/7 - 2016/7 Academic Advisor	Joshua Aleri (Completed) , University of Melbourne Thesis/Project Title: Evaluating high and low immune response in pasture-based cattle in Australia Present Position: Faculty at the University of Melbourne
2013/4 - 2016/4 Academic Advisor	Neda Barjestah (Completed) , University of Guelph Thesis/Project Title: Avian Influenza and Immune Response. Present Position: Faculty at the University of Montreal
2010/1 - 2016/10 Principal Supervisor	Lauri Wagter-Lesperance (Completed) , University of Guelph Thesis/Project Title: Genetic regulation of high and low immune responding dairy cattle Present Position: Research Associate
2009/1 - 2017/1 Principal Supervisor	Marlene Paibomesai (Completed) , University of Guelph Thesis/Project Title: Genetic and epigenetic regulation regulation of bovine immune response Present Position: Dairy Specialist for OMAFRA

Post-doctorate [n=4]

2017/9 - 2020/9 Co-Supervisor	Alexandra Livernois (Completed) , University of Guelph Thesis/Project Title: Breeding Livestock for Climate Resilience Present Position: Scientist
2017/2 - 2019/1 Principal Supervisor	Lauri Wagter-Lesperance (Completed) , University of Guelph Thesis/Project Title: High Immune Response Technology Present Position: Project Lead and Regulatory Affairs Manager, Ontario Veterinary College

2016/1 - 2017/4 Principal Supervisor	Prithy Rupa (Completed) , University of Guelph Thesis/Project Title: Examining the utility of the High Immune Response Technology for use in commercial Swine herds Present Position: industry researcher
2016/1 - 2019/9 Principal Supervisor	Saeid Tabatabaei (Completed) , University of Tehran Thesis/Project Title: Genetic regulation of high and low immune response of diary cattle Present Position: gradulate student

Research Associate [n=5]

2019/2 - 2022/12 Principal Supervisor	Lauri Wagter-Lesperance (In Progress) , Ontario Veterinary College Thesis/Project Title: High Immune Response Technology Present Position: research associate
2018/12 - 2022/12 Principal Supervisor	Douglas Hodgins (In Progress) , University of Guelph Thesis/Project Title: Genetic Selection for Disease Resistance: Adapting Immunity+ /High Immune Response (HIR) Technology for Application in the Beef Industry Present Position: research associate
2014/9 - 2022/10 Principal Supervisor	Julie Schmied (In Progress) , University of Guelph Thesis/Project Title: High Immune Response technology for use in commercial swine herds: A broad based approach to disease resistance & Translation of the HIR Technology for use in Angus Beef Cattle Present Position: research associate
2014/5 - 2019/5 Co-Supervisor	Heba Atalla (Completed) , University of Guelph Thesis/Project Title: Assessing the bioactivity of immune-related microRNA in colostrum and milk from high and low immune responder cows Present Position: Lab Manager/Technician
2009/9 - 2018/11 Co-Supervisor	Douglas Hodgins (Completed) , University of Guelph Thesis/Project Title: Genetic Selection for Disease Resistance: Adapting Immunity+ /High Immune Response (HIR) Technology for Application in the Beef Industry Present Position: research associate

Technician [n=6]

2021/2 - 2023/12 Principal Supervisor	Danielle Naylor (In Progress) , University of Guelph Thesis/Project Title: Immunological and microbiome properties of bovine colostrum Present Position: research technician, university of Guelph
2020/9 - 2022/12 Principal Supervisor	Nasrin Satayesh Husseini (In Progress) , University of Guelph Thesis/Project Title: High Immune Response Technology for Cattle Present Position: research technician, university of Guelph
2019/5 - 2023/10 Principal Supervisor	Heba Atalla (In Progress) , University of Guelph Thesis/Project Title: General lab management Present Position: Research Lab Manager, university of Guelph
2017/10 - 2019/6 Principal Supervisor	Marnie McKechnie (Completed) , University of Guelph Thesis/Project Title: Genetic regulation of bovine immunity Present Position: Nursing resident
2014/9 - 2023/9 Principal Supervisor	Natasha Gallo (In Progress) , University of Guelph Thesis/Project Title: General Lab Managment Present Position: research technician, university of Guelph

2010/1 - 2019/12 Principal Supervisor	Leah Read (Completed) , University of Guelph Thesis/Project Title: General Lab Management Present Position: unknown, unknown

Event Administration

2020/1 - 2023/1	Scientific Committee Member, International Veterinary Immunology Symposium, Conference, 2020/8 - 2023/8
2020/1 - 2022/10	Member of planning committee, International Society for Developmental Origins of Health and Disease (DOHaD), Conference, 2021/10 - 2022/10
2016/8 - 2018/7	Member of Hosting Country, International Society of Animal Genetics 2018 to be held in Canada, Conference, 2018/7 - 2018/7
2015/1 - 2018/7	Committee Member, 30th World Buiatrics Congress, Japan, Conference, 2018/7 - 2018/7
2017/1 - 2018/2	Chair for Disease Resistance, World Congress on Genetics Applied to Livestock Production: New Zealand 2018, Conference, 2018/2 - 2018/2

Editorial Activities

2012/1 - 2022/7	Editorial Board, Iranian Journal of Immunology, Journal
1990/1 - 2022/7	Editorial Board, Animal Biotechnology, Journal

Expert Witness Activities

2022/6 - 2022/12	Expert witness, Queen's Bench Alberta, Canada, Calgary Alberta Expert witness in immunology,
2021/9 - 2022/7	Expert witness, COURT OF QUEEN'S BENCH OF ALBERTA, JUSTICE CENTRE for CONSTITUTION, Canada, Edmonton Immunology expert
2021/9 - 2022/7	Expert witness, Juror Selection Case, ONTARIO SUPERIOR COURT OF JUSTICE (Toronto Region), Canada, Toronto Immunology expert

Organizational Review Activities

2014/1 - 2022/12	Ad hoc Reviewer, American Association of Dairy Science Ad hoc reviewer recognized by ADSA
2010/7 - 2020/12	Ad hoc reviewer, NSERC Ad hoc reviewer for NSERC grants as requested
2010/1 - 2020/12	Ad hoc Reviewer, Journals: Vet Immunol Immunopathol, BMC Immunol, BMC Genomics etc. Act as ad hoc reviewer for a number of journals including but not limited to Journal of Dairy Science, Canadian Journal of Vet Research. BMC Genomics and BMC Immunology
2014/1 - 2019/12	OMAFRA HQP Review Panel Member, Government of Ontario Panel Member for Reviewing and Selection of Annual OMAF HQP Graduate Scholarship Applications

International Collaboration Activities

2016/1 - 2020/12	Collaborator, Australia This is a collaboration in the area breeding disease resistant livestock based on enhanced immune responses that stemmed from earlier collaborations with this group. The PI is Dr Brad Hine at CSIRO. Other collaborators are Drs Jenny Pyrce and Andrew Fisher at University of Melbourne.
2016/3 - 2018/3	Collaborator, New Zealand This is a collaboration with Dr. Shannon Clark at AgResearch in Invermay, New Zealand. The project involves testing the High Immune Response Technology for use in NZ dairy sheep. A grant proposal has been submitted.
2013/6 - 2017/12	Collaborator, Australia Research collaboration with scientists at University of Melbourne and CSRIO in Armidale to evaluate immune response in pasture-based cattle. Activities include serving on a graduate student committee and hosting students for training in my lab as part of their training.

Committee Memberships

2020/1 - 2022/7	Committee Member, Steering and Scientific Committee, Canadian Covid Care Alliance
2015/1 - 2022/7	Co-chair, Health and Safety Committee - Department of Pathobiology and Animal Health Laboratory, University of Guelph
2014/1 - 2018/7	Committee Member, 30th World Buiatrics Congress Advisory Committee, World Buiatrics Congress

Other Memberships

1990/1 - 2022/12	Member, American Association of Veterinary Immunologists
1990/1 - 2022/12	Member, American Association of Animal Science
1990/1 - 2022/12	Member, International Society of Animal Genetics
1990/1 - 2022/12	Member, American Association of Dairy Science
1990/1 - 2022/12	Member, Canadian Society for Immunology

Presentations

1. (2022). Naturally acquired immunity. Woodbridge Science Panel, Woodbridge, Canada
   Invited?: Yes, Keynote?: No
2. (2022). Naturally acquired immunity. Parliament Hill Event, Ottawa, Canada
   Invited?: Yes, Keynote?: No
3. (2022). Immunoceuticals for Health. Canadian Covid Care Alliance RoundTable, Online, Canada
   Invited?: Yes, Keynote?: No
4. (2022). Infection and Immunity to SARS-CoV-2. Covid-19 2nd World Congress of Doctors for Life and the World Council for Health, Iguazu Falls, Brazil
   Invited?: Yes, Keynote?: No
5. (2022). Immunoceuticals for health. Canadian Centre for Learning, Online, Canada
   Invited?: Yes, Keynote?: No

6. (2022). Naturally acquired immunity. Fergus Supper Club Presentation, Fergus, Canada
Invited?: Yes, Keynote?: No

7. (2022). Naturally acquired immunity. Toronto Police Association, Online, Canada
Invited?: Yes, Keynote?: No

8. (2022). Immunoceuticals for Health. ReFound Ed, New Market, Canada
Invited?: Yes, Keynote?: No

9. (2021). Infection and Immunity to SARS-CoV-2. Covid-19 1st World Congress of Doctors for Life and the World Council for Health, Brazil
Invited?: Yes, Keynote?: No

10. (2020). HIR™/Immunity+ Technology. Private Industry Update to Semex Canada, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

11. (2020). High Immune Response (HIR™) Technology. Private industry presentation to Canadian Angus Association, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: No

12. (2020). Genetic Selection for Improving Livestock Health: HIR™ and Other Technologies. Academy of Dairy Veterinary Consultants Meeting, Portland, United States
Main Audience: Knowledge User
Invited?: Yes, Keynote?: No

13. (2020). Genetic Selection for Improving Livestock Health: High Immune Response Technology. Feedlot Health Management Services Meeting, Okotoks, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: No

14. (2020). Breeding Livestock for Resilience: The High Immune Response Technology. FarmSmart Conference, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

15. (2020). Genetic and Genomic Selection to Improve Livestock Health, Welfare and Productivity: High Immune Response Technology. American Association of Bovine Practitioners Webinar, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: No

16. (2019). Understanding Genetics, Genomics and Epigenetic regulation of the Bovine Immune System. American College of Veterinary Internal Medicine Forum, Phoenix, United States
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

17. (2019). Immunogenetic control of calf health and bovine mammary health. Private Industry Update to Semex Canada, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

18. (2019). Genetic and Genomic Approaches to Selecting Cattle for Improved Immunity. Private Industry Update to Semex Canada, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

19. (2019). Genetic control of specific and natural antibody production in Canadian Holsteins. Animal Genetics and Diseases, Hinxton, United Kingdom
Main Audience: Researcher
Invited?: No, Keynote?: No

20. (2019). The High Immune Response and other Genomic Technologies for Health. American College of Veterinary Internal Medicine Forum, Phoenix, United States
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

21. (2018). Genome-wide Association and Functional Annotation of Positional Candidate Genes for Immune Response in Canadian Dairy Cattle. World Congress of Genetics Applied to Livestock Production, Auckland, New Zealand
Main Audience: Researcher
Invited?: Yes, Keynote?: No

22. (2018). Evaluation of Milk and Colostrum Quality of HIR-Classified Cattle. Private Industry Presentation to GayLea Canada, Guelph, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: Yes

23. (2017). Genetic Regulation of Immune Response & Implications to Disease: The High Immune Response (HIR™) Technology. Spain's National Association of Bovine Specialists (ANEMBE), XXII Congress, Pamplona, Spain
Main Audience: Researcher
Invited?: Yes, Keynote?: No

24. (2017). Practical Implications of Breeding for Immunity in Dairy and Beef Cattle: A Short Summary. Spain's National Association of Bovine Specialists (ANEMBE), XXII Congress, Pamplona, Spain
Main Audience: Researcher
Invited?: Yes, Keynote?: No

25. (2017). Practical Implications of Breeding for Immunity in Dairy and Beef Cattle: A Short Summary. Guest Seminar: University of Madrid, Madrid, Spain
Main Audience: Researcher
Invited?: Yes, Keynote?: No

26. (2017). Genetic Regulation of Immune Response & Implications to Disease: The High Immune Response (HIR™) Technology. Guest Seminar: University of Madrid, Madrid, Spain
Main Audience: Researcher
Invited?: Yes, Keynote?: No

27. (2016). High Immune Response Technology and Breeding Selection. Dairy Strong Conference, Madison, Wisconsin, United States
Invited?: Yes, Keynote?: No

28. (2016). Genetic & Genomic Selection to Improve Health of Dairy Cattle: The High Immune Response (HIR™) Technology. Dairy Research and Innovation Day, Guelph, Ontario, Canada
Main Audience: Knowledge User
Invited?: Yes, Keynote?: No

29. (2016). Immunogenetics Approaches to Improving Livestock Heath: The High Immune Response™ (HIR) Technology. University of Waikato and AgrResearch. Ruakura Campus seminar, Hamilton, New Zealand
Main Audience: Researcher
Invited?: Yes, Keynote?: No

30. (2016). Immunogenetics Approaches to Improving Livestock Heath: The High Immune Response™ (HIR) Technology. Invermay AgrResearch Centre. Main Campus seminar, Invermay, New Zealand
Invited?: Yes, Keynote?: No

31. Dr Julie Schmied (main presenter). (2016). Breeding Livestock for Disease Resistance. Livestock Research Innovation Corporation (LRIC) Annual General Meeting – Disruptive Technologies for Livestock, Guelph, Canada
Main Audience: Decision Maker
Invited?: Yes, Keynote?: No

32. (2016). Genetic & Genomic Selection to Improve Health of Dairy Cattle: The High Immune Response (HIR™) Technology. IP and Entrepreneurship Workshop. University of Guelph, Guelph, Ontario, Canada
Invited?: Yes, Keynote?: No

33. (2016). Immunogenetics Approaches to Improving Dairy Heath: The High Immune Response™ (HIR) Technology. Iowa State University Animal Science Department Seminar, Ames, Iowa, United States
Main Audience: Researcher
Invited?: Yes, Keynote?: No

34. (2016). Immunogenetics Approaches to Improving Livestock Heath: The High Immune Response™ (HIR) Technology. University of Melbourne Veterinary School seminar, Melbourne, Australia
Main Audience: Researcher
Invited?: Yes, Keynote?: No

35. (2016). Adapting the High Immune Response (HIR™) Technology to Improve Beef Cattle Health. OMAFRA Gryphon's LAAIR Showcase, Guelph, Ontario, Canada
Invited?: Yes, Keynote?: No

36. (2016). Immunogenetics Approaches to Improving Livestock Heath: The High Immune Response™ (HIR) Technology. AgrResearch Otago Campus seminar, Mosgiel, New Zealand
Main Audience: Researcher
Invited?: Yes, Keynote?: No

37. (2016). Breeding Livestock for Disease Resistance - A Scientific Journey. Iowa State University, Animal Science Graduate Student Mentor Breakfast Seminar, Ames, Iowa, United States
Invited?: Yes, Keynote?: No

38. (2016). Immunogenetics Approaches to Improving Livestock Heath: The High Immune Response™ (HIR) Technology. La Trobe University seminar, Melbourne, Australia
Main Audience: Researcher
Invited?: Yes, Keynote?: No

Broadcast Interviews

2022/06/16 - 2022/07/27	Immunoceuticals for Health, Dr. Julie Ponesse Publications, The Democracy Fund
2022/02/12 - 2022/07/27	Naturally acquired immunity, Issues, Faytene TV
2016/01/08 - 2016/06/14	Bovine Immunity, Semex Immunity+ at Schwab Dairy, https://www.youtube.com/watch?v=KRN6r-v9mts
2013/05/07 - 2016/06/14	High Immune Response, Agri Food and Rural Link - University of Guelph, https://www.youtube.com/watch?v=bPgTokY0630
2012/12/04 - 2016/06/14	Immunity+, Youtube video by Semex Alliance, https://www.youtube.com/watch?v=skttmww8ygc

Text Interviews

2020/10/01	Helping Ontario beef producers make better herd management and breeding decisions, Ontario Beef Magazine
2018/05/22	High Immune Response technology improves genetics and herd health, M2 Magazine: Magazine for Mastitis and Milk Quality for the Dairy Professional
2017/09/28	Breeding cows with superior immune response, Dairy Global Digital Magazine

2017/07/25	Helping pigs to be better prepared for disease pressure, Pig Progress Digital Magazine
2016/06/30	Bred for Healthier Living, University of Guelph, Food Institute Webpage Article

Patents

1. BOVINE MONOCYTE-DERIVED MACROPHAGE IN CULTURE SYSTEM AND METHODS FOR MEASURING INNATE IMMUNITY.Canada. 62/878,3770. 2019/09/03.
   Patent Status: Pending
   Inventors: Mallard and Emam
   This method is being licensed to Canadian cattle breeding company. Previous patents from Mallard et al have also been licensed for use by Canada's largest dairy genetics company, the Semex Alliance. This new patent adds breadth and utility to existing patents in the area of breeding livestock for health.

Licenses

1. BOVINE MONOCYTE-DERIVED MACROPHAGE IN CULTURE SYSTEM AND METHODS FOR MEASURING INNATE IMMUNITY PCT/CA2020/050997
   Granted
   Filing Date: 2020/07/17
   A license to use this patented technology to measure nitric oxide in bovine monocytes and related trade secrets has been granted to the Canadian corporation, the Semex Alliance. Although the patent is still pending the license for use has been granted.

This is Exhibit "**B**" to the Affidavit of

Bonnie Mallard, sworn before me on

U of G Immunologist Has Concerns Over COVID-19 Vaccine Candidates

Prof. Byram Bridle

Two drug makers recently announced promising interim results for two COVID-19 vaccine candidates, but a University of Guelph viral immunologist says he has reservations.

Prof. Byram Bridle studies oncolytic viruses (viruses that target cancer cells) in U of G's Department of Pathobiology. He recently received provincial research funding to adapt the technology to develop a vaccine against SARS-CoV-2, the pandemic coronavirus.

Like many others, Bridle said he worries that Pfizer and Moderna released their interim test results as a press release. Without full scrutiny of the results, he said, many questions are left unanswered.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

"Not enough data has been released to know how well the vaccine prevents COVID-19, or if it can weaken symptoms," he said, "nor do we know how protective the vaccine will be for those who are most susceptible to severe cases."

For Bridle, a larger concern is the lack of data on the immune response offered by the vaccines, which are called subunit vaccines because they use a fragment of the virus to trigger an immune response.

"Subunit vaccines like these can be misinterpreted by the immune system as an extracellular pathogen," he said. "That creates the possibility that those who receive such a vaccine might have a 'bias' imprinted on their immune system that could cause them to respond sub-optimally to natural infections with future coronaviruses."

Bridle said the companies provided no data about the vaccine's effect on immunological memory, "which is the entire point of a vaccine. If the memory response is weak and wanes too quickly, those who receive the vaccine will not be protected over the long term."

He recently co-wrote a commentary on this topic for *Conversation Canada* with pathobiology professor Shayan Sharif, associate dean of research and graduate studies in U of G's Ontario Veterinary College.

Bridle is available for interviews this week.

U of G Vaccine Researcher Makes Headlines

Prof Byram Bridle

Prof. Byram Bridle, with the Department of Pathobiology at U of G's Ontario Veterinary College, appeared Sunday on *Global TV's The West Block* with Mercedes Stephenson for a segment on whether hopes for a COVID-19 vaccine within the next year are misplaced.

Bridle told the show that Canadians need to come to terms with how unlikely such a time frame is.

"I'm not going to say it's impossible, but I would say it's highly improbable," he said. "...Everybody wants hope, and the reason why I'm speaking out, though, is that false hope can be really problematic."

Bridle also spoke to *The Globe and Mail* for an article about it's important for most people to get the vaccine once it's available, to build "herd immunity." Bridle noted that he is worried that rushing a vaccine out to the market could undermine public trust in that vaccine which might lead to poor uptake of the vaccine.

"As soon as you use terms like 'warp speed,' it creates the impression that corners are being cut and a lot of people will question the safety of the vaccine," he said.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice
Court File No./N° du dossier du greffe : CV-22-00691880-0000

Bridle raised similar concerns in a recent *Conversation Canada* commentary he wrote with pathobiology colleague Prof. Shayan Sharif, associate dean of research and graduate studies at OVC. In that piece, they argued that it may not be possible to develop an effective COVID vaccine at "warp speed."

"We contend that a safe and effective vaccine against COVID-19 most likely cannot be made available to the public in time to make a substantial difference to the natural outcome of this pandemic," they wrote.

Bridle's team was one of 15 research teams across Ontario that recently received rapid provincial research funding to pursue research to develop a vaccine against the pandemic virus. They hope to adapt technology they developed that uses viruses to deliver cancer therapies.

Their plan is to develop avian and adenoviruses that could deliver proteins that would help humans fight off the coronavirus that causes COVID-19.

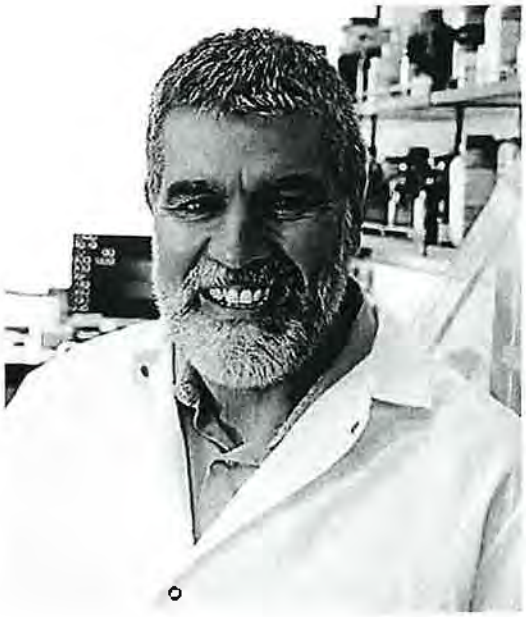
The Guardian Consults Virologist on Children's Immunity Concerns



Dr. Byram Bridle

Dr. Byram Bridle, a professor of immunology with the Department of Pathobiology at U of G's Ontario Veterinary College, spoke to *The Guardian* newspaper in the U.K. about whether extended quarantines might be harmful to children's immune systems.

Bridle said he's concerned that limiting children's exposure to the natural world, as has been done often in the last year, could lead to a rise in immunological disorders in children. He noted that the immune systems of young children go through an important period of immune system development before they reach the age of six.

Bridle studies oncolytic viruses and has received provincial research funding to adapt technology to develop a vaccine against SARS-CoV-2, the coronavirus that causes COVID-19.

Immunologist Pens Commentary on Kids' Health in COVID-19

Dr. Byram Bridle

Dr. Byram Bridle, a professor of immunology with the Department of Pathobiology at U of G's Ontario Veterinary College, provided a commentary for the *Conversation Canada* about the potential health effects for children who have remained indoors for most of the last year because of the COVID-19 pandemic.

He argued that kids who have been living largely in sanitized homes may be at greater risk of developing hypersensitivities and autoimmune diseases.

"An unfortunate and under-appreciated long-term legacy of this pandemic will likely be a cluster of 'pandemic youth' that grow up to suffer higher-than-average rates of allergies, asthma and autoimmune diseases. This will hold true for children in all countries that enacted isolation policies," Bridle wrote.

The commentary was re-posted on *Business Insider*, the *National Post*, the *Philippine Canadian Inquirer* and elsewhere. *Conversation Canada* has also translated the

The Office of Research oversees a $187 million research enterprise across seven colleges, our regional campus at Ridgetown, 15 research centres, and the University of Guelph/Ontario Ministry of Agriculture, Food and Rural Affairs Agreement. We are committed to supporting the research programs of University of Guelph faculty across all disciplines.

This is Exhibit "D" to the Affidavit

of Bonnie Mallard, sworn before me

on this 15th day of December 2023

A Commissioner for Taking Affidavits

Amina Sherazee Barrister and Solicitor

March 3, 2021

Dear Professor Charlotte Yates, President and Vice-Chancellor, and **Professor Gwen Chapman**, Interim Provost and Vice-President (Academic):

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought (*i.e.* acquisition of immunity). In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have been commissioned by the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area. Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses. Among the many reasons for this is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to allow SARS-CoV-2 to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada. It has become clear that we can't continue to rely on continual lockdowns. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. **It is from this perspective that we would like to recommend the following core strategies to support re-opening the University of Guelph campus to in-person learning in the Fall 2021 semester:**

1. **Offer comprehensive and sensitive testing for evidence of seroconversion (antibodies) against SARS-CoV-2.** Ever-accumulating data demonstrate that both naturally acquired, and vaccine-induced immunity can provide at least some level of protection from reinfection from the parental and current variant forms of SARS-CoV-2. Evidence of protective immunity either prior to and/or after vaccination would provide valuable information to guide decisions. This testing should be offered to members of the university that are both on- and off-campus. Several options for antibody testing are currently available in Canada. For example, LifeLabs currently has a test available. Even better, we have a colleague at the University of British Columbia who has developed the most comprehensive and sensitive test for seroconversion that we are currently aware of. Through collaboration with this colleague, we would be happy to assist with getting a local lab (possibly our own Animal Health Laboratory, which has an excellent quality control program and experience getting novel tests up and running) set-up to run this cutting-edge test.
2. **Offer strategically prioritized vaccinations.** Vaccination against SARS-CoV-2 should be offered to individuals wanting to return to campus. Prioritization should be based on risk of an infection progressing to disease (*i.e.* COVID-19). If doses are limited, vaccines would best be used in individuals with no evidence of immunity (based on testing in highlighted in point #1). Importantly,

vaccines should be administered precisely according the protocol that was used to have them approved for emergency use until further data is available on alternative protocols. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented evidence of it being relatively ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf). Vaccinations should be offered to university community members that are both on- and off-campus.

3. **Offer rapid antigen screening tests to detect the presence of SARS-CoV-2.** This is currently being tested on campus, and if successful, it would be logical to implement this approach more widely. It is very convenient for the workplace and should be offered to university community members that are both on- and off-campus.
4. **Offer off-campus learning/working accommodations for high-risk individuals.**
5. **Consider implementing supplemental testing.** Additional tests could help manage COVID-19 on-campus. For example, testing wastewater from buildings on campus, with an emphasis on residences could help identify 'hot spots'.
6. **Consider incorporating comprehensive data collection in consultation with our Research Ethics Board.** A lack of concerted efforts to collect comprehensive data sets has slowed the progress of research in many jurisdictions in Canada. The University of Guelph could provide a detailed analysis to support a return to campus at other institutions. Our Department of Population Medicine would be well-equipped to oversee this type of data collection. However, the rollout of vaccines and tests should not be delayed for establishing such a data collection infrastructure; rather, the infrastructure for research-quality data collection could interface with the rollout when it is ready.

Note: Implementation of suggestions 1-5 could have an impact on public health directives. Specifically, it would facilitate discussions around reduced physical distancing. Reducing physical distancing from two meters to one meter in classrooms could have a major positive impact on returning to in-person learning.

We would be happy to offer advice as our campus community moves forward. Specifically, Dr. Bridle is willing to serve on any relevant advisory committees and/or he can be a point of contact for our group, with whom he consults regularly. We also have many colleagues in the fields of virology, immunology, and public health at a variety of institutions that we consult with. We look forward to hearing your thoughts about the University of Guelph showing leadership among the academic community in getting students back to in-class learning.

Sincerely,

Dr. Byram W. Bridle
Associate Professor of Viral Immunology
E-mail: bbridle@uoguelph.ca

Dr. Sarah K. Wootton
Associate Professor of Virology

Dr. Bonnie Mallard
Professor of Immunology

Dr. Niel Karrow
Professor of Immunology

March 5, 2021

Dear Dr. Nicola Mercer, Medical Officer of Health and CEO of Wellington-Dufferin-Guelph Public Health:

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought (*i.e.* acquisition of immunity). In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have been commissioned by the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive and in-depth expertise in this area. Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses. Among the many reasons for this is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to allow SARS-CoV-2 to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada. It has become clear that we can't continue to rely on continual lockdowns. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. **It is from this perspective that we would like to recommend the following core strategies to support re-opening the City of Guelph and the surrounding regions by this Fall:**

1. **Offer comprehensive and sensitive testing for evidence of seroconversion (antibodies) against SARS-CoV-2.** Ever-accumulating data demonstrate that both naturally acquired, and vaccine-induced immunity can provide at least some level of protection from reinfection from the parental and current variant forms of SARS-CoV-2. Evidence of protective immunity either prior to and/or after vaccination would provide valuable information to guide decisions. Several options for antibody testing are currently available in Canada. For example, LifeLabs currently has a test available. Even better, we have a colleague at the University of British Columbia who has developed the most comprehensive and sensitive test for seroconversion that we are currently aware of. Through collaboration with this colleague, we would be happy to assist with getting a local lab (possibly our own Animal Health Laboratory, which has an excellent quality control program and experience getting novel tests up and running) set-up to run this cutting-edge test.
2. **Offer strategically prioritized vaccinations.** Prioritization should be based on risk of an infection progressing to disease (*i.e.* COVID-19). If doses are limited, vaccines would best be used in individuals with no evidence of immunity (based on testing highlighted in point #1). Importantly, vaccines should be administered precisely according to the protocol that was used to have them approved for emergency use until further data is available on alternative protocols. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented

evidence of it being relatively ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf).

3. **Offer rapid antigen screening tests to detect the presence of SARS-CoV-2.** This is currently being tested on the University of Guelph campus, and if successful, it would be logical to implement this approach more widely. It is very convenient for the workplace.
4. **Offer accommodations for remote working/learning for high-risk individuals.**
5. **Consider implementing supplemental testing.** Additional tests could help manage COVID-19. For example, testing wastewater from buildings, with an emphasis on high-density housing and workplaces could help identify 'hot spots'.
6. **Consider incorporating comprehensive data collection in consultation.** A lack of concerted efforts to collect comprehensive data sets has slowed the progress of research in many jurisdictions in Canada. The Wellington-Dufferin-Guelph Public Health in conjunction with the University of Guelph could provide a detailed analysis to support return-to-work and return-to-school policies at other institutions. Our Department of Population Medicine would be well-equipped to oversee this type of data collection. However, the rollout of vaccines and tests should not be delayed for establishing such a data collection infrastructure; rather, the infrastructure for research-quality data collection could interface with the rollout when it is ready.

Note: Implementation of suggestions 1-5 could have an impact on public health directives. Specifically, it would facilitate discussions around reduced physical distancing. Reducing physical distancing from two meters to one meter in workplaces and classrooms could have a major positive impact on returning to in-person work and learning.

We would be happy to offer advice as our regional community moves forward. Specifically, Dr. Bridle is willing to serve on any relevant advisory committees and/or he can be a point of contact for our group, with whom he consults regularly. We also have many colleagues in the fields of virology, immunology, and public health at a variety of institutions that we consult with. We look forward to hearing your thoughts about the Wellington-Dufferin-Guelph Public Health Unite showing leadership within Canada in getting local citizens back to in-person work and in-class learning.

Sincerely,

Dr. Byram W. Bridle

March 16, 2021

Dear Fellow Canadians:

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought, which is acquisition of immunity against the virus SARS-CoV-2. In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have received funding from the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area.

Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses.

Among the many reasons for this virus becoming endemic is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to potentiate SARS-CoV-2 being able to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada.

It has become clear that we can't continue to rely on continual lockdowns due to the impact on mental health, delays to other medical treatments, a sinking economy, and so on. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. It is also important to remember that the majority of cases of COVID-19 in Canada are mild-to-moderate, and the death rate has been quite low (22,514 deaths out of 914,697 cases or 592/million as of March 16 2021 - Coronavirus Dashboard [ncov2019.live]). Sadly, at least 70% of those deaths have been in people over 80 years of age, in long-term care (Dr. R. Bibby, Sociologist, University of Lethbridge; http://www.reginaldbibby.com/specialcovid19analyses.html). On the upside, there is now also good evidence that the majority of those recovered from COVID-19 have protective immunity (reviewed by Sette and Crotty, Adaptive immunity to SARS-CoV-2 and COVID-19, Cell (2021), DOI: https://doi.org/10.1016/j.cell.2021.01.007).

It is from this perspective that we have been advocating for several core strategies to support re-opening our country to in-person work and learning. An important aspect of this is offering strategically prioritized vaccinations. Specifically, we have been advocating for the **administration of safe and effective COVID-19 vaccines according the protocol that was used to have them approved** for emergency use, until further data is available and reviewed and approved by Health Canada to support alternative protocols. In support of this goal, we have two recommendations:

1. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented evidence of it being ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. Specifically, it was shown to be only 10% effective against the South African variant, with the cut-off for approval being 50%. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf). Additionally, its use has been suspended in at least ten European countries until undesirable potential side-effects can be further investigated. For Ontarians, the Chief Medical Officer definitively stated in a letter to pubic health units in the province that individuals may opt out of receiving the AstraZeneca vaccine on the basis that it is admittedly of lower efficacy than the others (see the highlighted text on page 2 of the attached letter).

2. The intervals for the two-dose COVID-19 vaccines should adhere to what was officially approved by Health Canada and the manufacturers, which is 21- and 28-days for the Pfizer and Moderna vaccines, respectively. The rationale for this is presented below...

The history of Canada's move to extend COVID-19 intervals to an unprecedented four months.

Last week, the CBC launched a story to highlight the path that has led many jurisdictions in Canada to begin implementing an interval of up to four months for both the Pfizer and Moderna COVID-19 vaccines (https://www.cbc.ca/news/health/canada-covid-19-vaccine-delay-risk-1.5939134). It apparently began with a letter from an epidemiologist at the British Columbian Centre for Disease Control to the editor of *The New England Journal of Medicine* (https://www.nejm.org/doi/full/10.1056/NEJMc2036242). In this letter it was claimed that Pfizer failed to realize the efficacy of its own vaccine and that its effectiveness as a single-dose regimen is actually a remarkable 92%. It is important to note that this is based on an extrapolation of a statistically underpowered, biased, limited data set from a trial that was never designed to test single-dose efficacy. Further, the extrapolation required several assumptions to be made that may or may not be true; there simply is no empirical data to know either way.

What many do not realize is that the researchers for Pfizer published a rebuttal to this letter in which they stated: **"In response to Skowronski and De Serres: we would like to emphasize that alternative dosing regimens of BNT162b2 have not been evaluated."** Pfizer's own data has suggested that single-dose effectiveness might be just over 50%, with their admission of the caveat that their study was never designed to test this properly. Nonetheless, the idea that extended intervals will work well is being propagated, despite a lack of empirical evidence. Indeed, Dr. Bridle has confirmed via interviews with people coming out of local vaccine clinics that some of them are being told that a single dose has been shown to be 92% effective based on 'published data'. This is simply untrue and not the way science is supposed to work. The validity of alternative protocols is up for debate in the scientific community.

Any intervals that deviate from what Health Canada and the vaccine manufacturers have agreed to, represents experimentation, especially in the absence of any new validated data from a phase 3 clinical trial. However, in Ontario and many other jurisdictions in Canada, the change in the vaccine interval has been proposed. See the attached letter from Ontario's Chief Medical Officer as an example of this. In short, the intervals have been lengthened without sufficient empirical data to justify it. In contrast, the intervals provided by Health Canada are based on empirical data. The effectiveness of the two-dose regimens with 3- or 4-week intervals is known. The effectiveness of the two-dose regimens with any other interval is a 'best guess'. This background leads into a potentially more serious issue regarding informed consent...

Is informed consent being practiced properly in COVID-19 vaccine clinics?

In Ontario, the attached consent form should be hard-signed by everybody prior to receiving one of the experimental vaccines. Please note that this form requires a person to have read or to have read to them the vaccine information sheet (see the highlighted text on page 3 of the consent form). Please note the highlighted text on pages 4 and 6 of the vaccine information sheet that is appended to this letter. Consent is being given to receiving the dose at Health Canada's recommended interval of 3- (Pfizer) or 4-weeks (Moderna). No alternative intervals are described. Remarkably, however, many (if not most) attendees at the COVID-19 vaccine clinics are being told after receiving their first dose (*i.e.* once they are committed to the treatment) that they will likely have to wait up to four months to receive the second dose. **People are consenting to the 3-4-week interval** (3 weeks for Pfizer's vaccine; four weeks for the Moderna vaccine) **but are then being told that they cannot receive the second dose for another four months.** For those who would like to insist on receiving their vaccine as per Health Canada's recommended interval, we suggest you take a hard-copy of the vaccine information sheet to the clinic and have

them confirm that they will adhere to the protocol you are consenting to prior to letting them administer the first dose.

Why might the interval for two-dose vaccines matter?

Some proponents of lengthening the interval argue there can be no harm. However, there is some scientific basis for suggesting that lengthening intervals could cause harm: 1. The companies themselves suggest a single dose is significantly less efficacious than two doses. This could put individuals at prolonged risk of getting infected while waiting for the second dose. This could be a particular problem for those who are at high risk. 2. It is unknown if the duration of immunity (i.e. how long a person is protected) conferred by a single dose extends to four months; it is possible that there may be no protection at this point. 3. It is unknown if immunological memory conferred by the first vaccine will last long enough for a second dose, given four months later, to serve as a proper 'booster vaccine'. If a proper boost is not conferred, the two-dose effectiveness could be reduced below the 95% effectiveness shown with the approved interval. 4. Induction of long-term, relatively weak immunity could potentially promote the emergence of immune-evasive mutants. This would be similar to what has been observed over and over again with the emergence of dangerous antibiotic-resistant bacteria; it is potentiated by the misuse of the therapeutic agents designed to effectively treat the pathogens. Promotion of immune-evasive SARS-CoV-2 would put everyone at greater risk. Although these are cautionary possibilities, **they are no less valid than the speculations that led to adopting untested long intervals**. Given these are novel nucleic acid vaccine platforms, approved for emergency use only, it might be wise to err on the side of caution. The take-home message is: Longer intervals might be OK, but they also might create problems. We simply don't know yet. On this basis, **those who want to receive the vaccines according to how they were approved for emergency use should be entitled to this**. However, **public health officials seem to be over-riding this right, even though it contradicts their own informed consent procedure, Health Canada, and the vaccine manufacturers**.

With sincere concern for our fellow Canadians,

March 23, 2021

Dear Fellow Canadians:

Scientists Express Urgent Concerns Over Current COVID-19 Vaccine Policies

University Of Guelph Faculty Speak Up:

The following urgent concerns are being expressed by the following faculty members at the University of Guelph:

- Dr. Byram Bridle is a viral immunologist
- Dr. Bonnie Mallard is an immunologist
- Dr. Neil Karrow is an immunologist

Generally, policies for COVID-19 have been generated with relatively little consultation with immunologists, including viral immunologists. However, at its core, COVID-19 is a problem at the interface of immunology and virology.

This interface is both in terms of its pathogenesis and the primary solution being sought, which is acquisition of immunity against the virus SARS-CoV-2. In addition to our group having in-depth knowledge of these fields, Dr. Bridle received funding from the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area. Please note that information about COVID-19 vaccines is rapidly changing. The information presented below is accurate as of March 23, 2021.

Has The Goal To Flatten The Curve Been Forgotten?

Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks. The purpose was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed.

Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses.

Will SARS-CoV-2 Become Endemic?

Among the many reasons for this virus becoming endemic is the propensity of SARS-CoV-2 to mutate over time. This will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly focused immunity that targets a single protein known as the spike.

These two major issues will combine to potentiate SARS-CoV-2 being able to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada.

How Can We Live With This Virus While Still Maximizing Health And Safety?

It has become clear that we can't continue to rely on continual lockdowns due to impact on mental health, delays to other medical treatments, a sinking economy and so on. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities.

It is also important to remember that the majority of cases of COVID-19 in Canada are mild-moderate, and the death rate has been quite low (22,676 deaths out of 933,798 cases or 596/million people as of March 22, 2021 - Coronavirus Dashboard (ncov2019.live).

Sadly, at least 70% of those deaths have been in people over 80 years of age, in long-term care (Dr. R. Bibby, Sociologist, at the University of Lethbridge – Research of Reginald W. Bibby (reginaldbibby.com)).

On the upside, there is now also good evidence that the majority of those recovered from COVID-19 have protective immunity (reviewed by Sette and Crotty, Adaptive immunity to SARS-CoV-2 and COVID-19, Cell (2021), https://doi.org/10.1016/ j.cell.2021.01.007).

Therefore, we need to identify those with immunity from natural exposure using available antibody testing, and strategically prioritize those at highest risk, who need and want to be vaccinated, according to the manufacturers currently approved vaccination protocols.

How Can Vaccines Be Prioritized According To Manufacturers Approved Protocols?

It is from this perspective that we have been advocating for several core strategies to support re-opening our country to in-person work and learning. An important aspect of this is offering strategically prioritized vaccinations.

Specifically, we have been advocating for the administration of safe and effective COVID-19 vaccines according the protocol that was used to have them approved for emergency use, until further data is available and reviewed and approved by Health Canada to support alternative protocols.

In support of this goal, we have two recommendations:

1. Consideration should be given to avoiding the AstraZeneca vaccine, for which there is documented evidence of it being ineffective against the South African variant of SARS-CoV-2, which is now in Canada. It was only 10% effective against the South African variant, with the cut-off for approval being 50% (https://www.nejm.org/doi/full/10.1056/NEJMoa2102214?query=featured_home).

2. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf).

   For Ontarians, the Chief Medical Officer definitively stated in a letter to pubic health units in the province that individuals may opt out of receiving the AstraZeneca vaccine on the basis that it is admittedly of lower efficacy than the others (see the highlighted text on page 2 of the attached letter).

3. The intervals for the two-dose COVID-19 mRNA vaccines should adhere to what was officially approved by Health Canada and the manufacturers, which is 21- and 28-days for the Pfizer and Moderna vaccines, respectively. The rationale for this is presented below...

Why The Concern Over Changing The Manufacturers Approved Protocols?

The history of Canada's move to extend COVID-19 intervals to four months is unprecedented. Recently, the CBC launched a story to highlight the path that has led many jurisdictions in Canada to begin implementing an interval of up to four months for both the Pfizer and Moderna COVID-19 vaccines (https://www.cbc.ca/news/health/canada-covid-19-vaccine-delay-risk-1.5939134).

It apparently began with a letter from an epidemiologist at the British Columbian Centre for Disease Control to the editor of *The New England Journal of Medicine* (https://www.nejm.org/doi/full/10.1056/NEJMc2036242).

In this letter it was claimed that Pfizer failed to realize the efficacy of its own vaccine and that its effectiveness as a single-dose regimen is a remarkable 92%. It is important to note that this is based on an extrapolation of a statistically underpowered, biased, limited data set from a trial that was never designed to test single-dose efficacy. Further, the extrapolation required several assumptions to be made that may or may not be true; there simply is no empirical data to know either way.

What many do not realize is that the researchers for Pfizer published a rebuttal to this letter in which they stated: "In response to Skowronski and De Serres: **we would like to emphasize that alternative dosing regimens of BNT162b2 have not been evaluated.**" Pfizer's own data has suggested that single-dose effectiveness might be just over 50%, with their admission of the caveat that their study was never designed to test this properly.

Nonetheless, the idea that extended intervals will work well is being propagated, despite a lack of empirical evidence. Indeed, Dr. Bridle has confirmed via interviews with people coming out of local vaccine clinics that some of them are being told that a single dose has been shown to be 92% effective based on 'published data'. This is simply untrue and not the way science is supposed to work. The validity of alternative protocols is up for debate in the scientific community.

Notably, on March 22nd, Canada's chief science adviser, Dr. Mona Nemer, spoke out against lengthening dosing intervals for Canadian seniors, citing not only a lack of scientific evidence to support it, but even emerging evidence to contraindicate it (https://www.ctvnews.ca/health/coronavirus/research-doesn-t-back-vaccine-dose-delay-for-seniors-canada-s-chief-science-adviser-says-1.5358075).

Any intervals that deviate from what Health Canada and the vaccine manufacturers have agreed to, represents experimentation, especially in the absence of any new validated data from a phase 3 clinical trial. However, in Ontario and many other jurisdictions in Canada, the change in the vaccine interval has been implemented.

See the attached letter from Ontario's Chief Medical Officer as an example of this. In short, the intervals have been lengthened without sufficient empirical data to justify it. In contrast, the intervals provided by Health Canada are based on empirical data. The effectiveness of the two-dose regimens with three-

or four-week intervals is known. The effectiveness of the two-dose regimens with any other interval is a 'best guess'. This background leads into another potentially serious issue regarding informed consent...

Is Informed Consent Being Practiced Properly In Canadian COVID-19 Clinics?

According to Ontario's Ministry of Health website, the attached consent form should be hand-signed by everybody prior to receiving one of the experimental vaccines. Please note that this form requires a person to have read or to have read to them the vaccine information sheet (see the highlighted text on page 3 of the consent form). Please note the highlighted text on pages 4 and 6 of the vaccine information sheet that is appended to this letter.

The Ontario Ministry of Health website appears to be requiring consent to be given to receiving the second dose of the mRNA vaccines at Health Canada's recommended interval of three- (Pfizer) or four-weeks (Moderna). No alternative intervals are described. Remarkably, however, most attendees at the COVID-19 vaccination clinics are being told that they cannot receive the second dose for another four months.

For those who would like to insist on receiving their vaccine as per Health Canada's recommended interval, we suggest you take a hard-copy of the vaccine information sheet to the clinic and have them confirm that they will adhere to the protocol you are consenting to prior to letting them administer the first dose.

WHY MIGHT THE INTERVAL FOR TWO-DOSE VACCINES MATTER?

Some proponents of lengthening the interval argue there can be no harm. However, there is some scientific basis for suggesting that lengthening intervals could cause harm:

1. The companies themselves suggest a single dose is significantly less efficacious than two doses. This could put individuals at prolonged risk of getting infected while waiting for the second dose. This could be a particular problem for those who are at high risk.

2. It is unknown if the duration of immunity (*i.e.* how long a person is protected) conferred by a single dose extends to four months; it is possible that there may be no protection at, or even before this point.

3. It is unknown if immunological memory conferred by the first vaccine will last long enough for a second dose, given four months later, to serve as a proper 'booster vaccine'. If a proper boost is not conferred, the two-dose effectiveness could be reduced below the 95% effectiveness shown with the approved interval.

4. Induction of long-term, relatively weak immunity could potentially promote the emergence of immune-evasive mutants. This would be similar to what has been observed over and over again with the emergence of dangerous antibiotic-resistant bacteria; it is potentiated by the misuse of the therapeutic agents designed to effectively treat the pathogens.

Promotion of immune-evasive SARS-CoV-2 would put everyone at greater risk. Although these are cautionary possibilities, they are no less valid than the speculations that led to adopting untested long

intervals. Given these are novel nucleic acid vaccine platforms, approved for emergency use only, it might be wise to err on the side of caution.

5. A pre-print of a relevant scientific article was posted on-line (https://www.medrxiv.org/content/10.1101/2021.03.03.21251066v1). It has not yet undergone peer review. However, we routinely review these kinds of articles and have concluded that the core data set appears to be valid. This article describes results of a study with the Pfizer vaccine. Importantly, the authors have concluded "since the majority of vaccinees did not obtain neutralizing antibody titers after the first vaccination, we suggest that **postponing a second vaccination with this vaccine is neither advisable for younger nor elderly populations**." In short, a single dose of Pfizer's vaccine would be expected to leave most people unprotected against SARS-CoV-2. Therefore, extending the interval to four months would not meet the goal of getting twice as many people partially protected, as our public health officials are claiming. Instead, it could cause large numbers of people to be left unprotected for a prolonged period.

What's the Take-Home Message?

A longer interval might be okay for the Moderna vaccine, but it also might create problems. We simply don't know yet. Cutting-edge data from a properly conducted scientific study suggested that a prolonged interval for the Pfizer vaccine is dangerous. On this basis, those who want to receive the vaccines according to how they were approved for emergency use should be entitled to this.

However, public health officials seem to be over-riding this right, even though it appears to contradict Health Canada, the vaccine manufacturers, Canada's chief science advisor, and the informed consent procedure posted on the Ontario Ministry of Health website.

Glen,

I was just sent even more tweets from you that slam my interview. This is absolutely disgusting. You do realize don't you that I could not possibly show the scientific basis for my statements on a radio show, right? Since you are 'just down the hall from me' why don't you drop by sometime for a real scientific debate. You are obviously the local expert on COVID-19 vaccines, not me. If you have issues, why not talk to me directly? Why, instead, are you slamming me behind my back and in public forums?

Glen,

Can you please explain your role in the smear campaign against me? Who is the scientist that made the website to slander me? I need this information now! ...or are you going to continue to revel in the harm being caused to a colleague that you are embarrassed about? If I do not receive a reply from you by noon on Monday, I will contact the police to see if they can get the information from you.

Subject: smear campaign

Dear Jeff and Shayan,

It has been brought to my attention that a smear campaign has been launched against me because I answered a question about COVID-19 vaccines that was posed to me by a radio show host. Everything I said is backed up by peer-reviewed scientific articles. Of course, however, I had no way to show these references in the context of a radio interview. FYI, this libelous website was set-up...

http://byrambridle.com/

Because of this I have found myself the victim of vicious attacks. This has forced me to cancel my commitment to a grant review panel for CIHR (reviews were due tomorrow [Mon.], the panel was to meet the week after). I have had to leave them and applicants short of eight reviews. This is a very embarrassing thing to do and reflects very poorly on me as a professional. I have also had to contact two editors to plead for extensions to submission deadlines for two manuscripts from my group that were due tomorrow (Monday). This is taking a toll on my mental and physical health. I should not have to be up at 2 in the morning on a Sunday having to deal with this. Thankfully, I have had numerous colleagues, both locally and from around the world jump to my defence. I have already been in contact with a legal team that has offered to investigate should I wish to follow through. There is a second lawyer who may be willing to help. Of incredible concern was this tweet that was forwarded to me....

https://twitter.com/glenpyle/status/1398810510234206210

Glen Pyle | #GetVaccinated on Twitter

"@maggieoutabout @DFisman @UofGuelphOAC It's not a hacker. The person who made it has contacted me. They are a scientist."

twitter.com

...I demand to know what Glen's role is in this. Did he condone this? Was he part of this? He certainly knows who made the website and did not speak out against it. The website also uses an article that Glen wrote to try to slam me. I will wait to see if this can be handled internally. However, I am ready to pull the trigger on a police investigation and getting a lawyer involved. Since I have had to, with enormous embarrassment, cancel my work obligations, I am now free most of Monday. I would like to deal with this ASAP. None of this adheres to the principle of academic freedom. To protect myself, I now feel obligated to disseminate the scientific sources of my comments. I am currently writing a comprehensive document to prove that the science underpinning my comments is legitimate. I should not be having to waste so much time and energy on something like this. I am disgusted. Especially if a colleague within OVC is involved in some way. I have never had anything but the most collegial interactions with Glen in the past. We served together on the Pet Trust grant review panel. Why didn't he use this public forum to condemn a vicious attack on a colleague???!!!??? Instead, he is implying that the slander is legitimate by assuring the public that it was written by a scientist that he can back-up. This has got very ugly very quickly.

Do you have any more information that you can provide to me?

What is the immediate next step?

Sincerely,
Byram

I'm glad to see that others thought it equally silly for you to discredit someone with zero evidence to back it up! Come on, you are not 10 years old anymore. Please act your age. Like it or not, I'm not going to conform to your way of thinking about the pandemic and I have scientifically valid reasons for it. I am allowed to be an independent critical thinker.

...what information are you referring to Scott? And what misinformation did I give? Interestingly, since your communication was in text, you had ample opportunity to describe: (a) what exactly you were rebutting in terms of the science I was interviewed about; and (b) citations to back-up your claim of misinformation. This is akin to saying "my colleague is giving misinformation and I can prove it with my lack of information to back up my claim". I gave a five-minute interview over the radio. You do realize that I can't show papers via the air waves, right? So what information are you criticizing? Did you have any idea what papers I was referring to? FYI, I have attached a brief report to back-up my very legitimate concerns for the health and safety of all Canadian children. I would be happy to debate with you anytime about COVID-19 vaccines if you like to do so. In the report that I have attached, please go to the link to Pfizer's own biodistribution data showing that their vaccine platform travels far and wide throughout the body and accumulates in many tissues. Also, see their report to the European Medicines Agency in which they admit that they have no pharmacokinetic/biodistribution data with the actual vaccine that is going into our children. These are basic studies that should always be done prior to any vaccine being used. Using this vaccine in children without proper biodistribution and additional

safety data that looks at the effect of depositing the vaccine into a plethora of tissues is scientific blasphemy. Do you really think, on this basis, that there are no legitimate safety issues that should be addressed? ...because I can tell you from years of experience that is not how one goes about developing a novel treatment with integrity.

Next time, before you go ahead and fuel a fire that is roasting a colleague, please consider talking to me to determine what my rationale is. What you did here was immature and disrespectful. Do you realize the harm this smear campaign is doing to me?

I must say, it's great to have colleagues like you and Glen around. It is creating a great collegial work environment.

Jeff and Shayan: is this behaviour from Glen and Scott going to be condoned? Jeff, you will recall that Scott already implied that I didn't have the right to hold an opposing view in a recent department meeting. In the current situation, it is ridiculous that I have to present a report to show my colleagues that I actually know what I'm talking about just so I can get them to leave me alone in the world of social media. I think that this harassment in the workplace needs to stop.

Sincerely,
Byram

COVID-19 Vaccines and Children:

A Scientist's Guide for Parents

by

Dr. Byram W. Bridle, PhD

Associate Professor of Viral Immunology

June 15, 2021

Canadian Covid Care Alliance
Alliance canadienne pour la prévention et prise-en-charge de la covid

EXECUTIVE SUMMARY

Pfizer BioNTech's COVID-19 mRNA vaccine has been *Authorized under an Interim Order* by Health Canada for use in Canadians as young as 12 years old, with mandatory commitments for the monitoring of long-term safety and efficacy. Authorization under an Interim Order means additional information is needed on the safety, efficacy, and quality of the vaccine, including in children and adolescents, to support the future full market approval and licensing of the vaccine.

There is some uncertainty regarding the long-term safety of Pfizer BioNTech's COVID-19 vaccine in all individuals, and especially in children, youth, and younger adults of child-bearing age. Indeed, some key safety studies appear to have been missed in the rush to roll out the vaccines, and more is being learned about the vaccines every day. For example, there was a previously wide-held assumption that vaccination with the mRNA vaccines is safe because it is a localized event in the body, with the vaccine remaining limited to the shoulder muscle following injection and triggering an immune response in the local lymph nodes. However, there is evidence that Pfizer's COVID-19 vaccine does not remain at the injection site. In fact, once injected, the vaccine contents appear to travel extensively throughout the body, to the brain and other sensitive tissues, such as bone marrow, spleen, liver, adrenal glands, ovaries *etc.* Whether these body sites are involved in producing the spike protein is not known, as this was never studied. Nonetheless, new data have been published that, following vaccination with the Moderna vaccine (an mRNA vaccine very similar to Pfizer's mRNA vaccine), the spike protein can enter the circulatory system. Presumably, this means the spike protein can travel extensively throughout the body. It is important to understand which organs are producing the spike protein, what factors result in the spike protein entering the circulation, how long the spike protein circulates, and in which body fluids (*e.g.*, semen, saliva, breast milk, urine) the spike protein is present. This information is incredibly important because recent data have come to light that the spike protein is "biologically active". This means that the spike protein is not just an antigen that is recognized by the immune system as being foreign. It means that the spike protein, itself, can interact with receptors throughout the body, called ACE2 receptors, potentially causing undesirable effects such as damage to the heart and cardiovascular system, blood clots, bleeding, and neurological effects. Although some might argue that the risk of the spike protein causing this type of damage is only a theoretical risk, when we are mass vaccinating a population of predominantly healthy people, including children, adolescents, and adults of child-bearing age, there is absolutely no room for avoidable error.

The current scientific uncertainties demand that the administration of Pfizer's COVID-19 vaccine to children, adolescents, and young adults of child-bearing age be paused until proper scientific studies that focus on the safety and pharmacokinetics and biodistribution of the vaccines and the vaccine-encoded spike protein can be conducted. Halting the vaccination can be done safely because:

- The risk of severe and potentially lethal COVID-19 in these specific populations is so low that we need to be very certain that risks associated with mass vaccination are not higher;
- Asymptomatic members of this population are not a substantial risk for passing COVID-19 to others; and

- There are effective early-treatment strategies for the very few children, adolescents, and young adults of child-bearing age who may be at risk of developing severe COVID-19, such as ivermectin, fluvoxamine, and budesonide.

It is not appropriate to use an "experimental" vaccine in a population group unless the benefit of vaccination exceeds the risk of vaccination in that population group. With risk of severe COVID-19 in children, adolescents, and young adults of child-bearing age already so low, the benefit of vaccinating these population groups with a vaccine for which neither the long-term safety nor efficacy is known cannot be concluded to exceed the risk. In other words, the risk of serious COVID-19 is so low in children, adolescents, and young adults of child-bearing age that the standards for safety must be set much higher for them.

Contents

Who is Dr. Bridle?

I am an Associate Professor of Viral Immunology in the Department of Pathobiology at the University of Guelph in Canada. My research program focuses on the development of vaccines to prevent infectious diseases and treat cancers, as well as studying the body's immune response to viruses. I teach several courses at the undergraduate and graduate levels on the topics of immunology, virology, and cancer biology. The overall aim of my research efforts is to develop safe and effective new therapies for people. Indeed, one of my previous cancer therapies progressed into four human clinical trials. I am also involved in training Canada's next generation of multidisciplinary researchers, especially in vaccinology. I received funding from the Ontario Government (COVID-19 Rapid Research Fund, Ministry of Colleges and Universities) and Government of Canada (Pandemic Response Challenge Program, National Research Council of Canada) to develop vaccines against COVID-19. The scope of this research is limited to the pre-clinical realm and is years away from being ready for testing in a clinical trial. Since I do not hold any commercial interests, this is not considered a conflict of interest that would preclude me from publishing my research findings. If that were the case, most researchers could never comment on topics relevant to their area of expertise, because they receive funding in that area. Further, my laboratory's vaccine vectors also express the spike protein of SARS-CoV-2. As such, what I am presenting here affects my vaccines as much as anyone else's. I also hold numerous grants in support of my cancer research and basic viral immunology research programs, including, but not limited, to the Canadian Institutes for Health Research, Natural Sciences and Engineering Research Council of Canada, Canadian Cancer Society, and Cancer Research Society. Since the COVID-19 pandemic was declared, I have been actively involved in providing fact-based; balanced, scientific answers to questions posed by the public to help them make fully informed decisions. This has included ~150 media engagements ranging from radio shows, published articles, and appearances on televised news programs, spanning the local to international scope. I was also an invited keynote speaker for two international conferences that focused on COVID-19 and served as an invited member of several COVID-19-focused discussion panels. Vaccinology is a sub-discipline of immunology. I teach the value of high-quality, well-validated, robustly safety-tested vaccines and promote their use. I consider vaccines that have been developed on a foundation of sound science to be the most efficient type of medicine; they have cost-effectively saved millions of people from sickness and/or death. However, I am concerned that the risk-benefit profile of SARS-CoV-2 vaccines currently being used in Canada and elsewhere may not be appropriate for the mass immunization of children, youth, and young adults of child-bearing age. My scientific reasoning substantiated by the peer-reviewed literature is contained within this guide.

What is the Canadian COVID Care Alliance (CCCA)?

The CCCA is an alliance of independent Canadian scientists, physicians and other health professionals, committed to providing top-quality and balanced evidence-based information to

the Canadian public about COVID-19 so that hospitalizations can be reduced, lives can be saved, and our country can be safely restored as quickly as possible.

Disclaimer

The comments in this guide are mine alone and do not necessarily reflect the opinions held by my academic institution or the agencies funding my research program. Nevertheless, these comments have been vetted and supported by many like-minded researchers and physicians associated with the CCCA.

Preamble

Although I have tried to be reasonably comprehensive in my presentation of relevant facts about COVID-19 vaccines, I could have written much more; hundreds of pages, in fact. However, I feel that the current content represents the most important information that parents will need to make informed decisions about vaccinating their children. As children in Canada who are 12 and older can be vaccinated without parental consent, this guide also serves to share information and encourage open discussions between parents and their older children, so that the choice to consent or not consent is truly "informed". There will be many people who will challenge the content of this guide. I respect others' opinions and decisions. I simply ask for similar respect in return. I am a public servant providing information for which I have substantial expertise. It is being done from the perspective of having a genuine concern for the well-being of Canadian youth. I urge everyone to follow the weight of validated scientific data. I ask you to challenge information that is accompanied by loose claims of being 'data from on the ground' or 'data from the front lines', which often lack scientific rigor and a 'big picture' perspective, especially in an era of extensive social media censorship. Follow the weight of the validated data when deciding which evidence is relevant and reliable in your decision-making process.

Important note: many treasured colleagues from within and outside Canada have helped me piece together this story. Without them, we would not have made all the scientific links that are described in this guide. As such, **I can take only partial credit for this work.** Instead, I am fronting a larger group of physicians and researchers; consolidating our conversations and sharing of scientific articles into my own words. Sadly, many of these experts and professionals currently feel the need to remain anonymous to protect themselves from potentially career-ending reprisals when objective scientific evidence is presented publicly.

I have included some citations and links for important statements to show that they are backed by sound science. In many cases, there are other scientific articles that could have been referenced. However, the purpose of this document is not to provide an exhaustive list of references, but rather to provide sufficient evidence to support my concerns. My goal is not to prove that Canada's COVID-19 vaccines are unsafe, but to highlight the substantial uncertainties that exist in the current base of safety evidence and my consequent discomfort with the mass

vaccination of our youth. The proper scientific process dictates that the burden of proof of safety is on vaccine manufacturers and health protection agencies. Most importantly, a lack of proof of harm is not proof of safety.

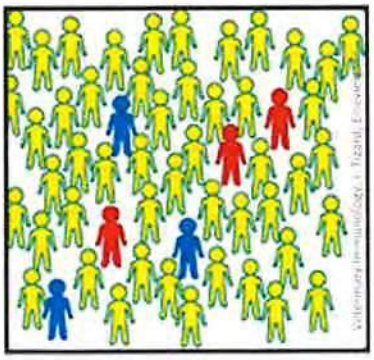
I first presented some of the information that is in this guide during a radio interview on May 27, 2021. This was a truncated ~five-minute sound bite that triggered a public smear campaign, including a slanderous website, a fake Twitter account, and harassment in the workplace. Nobody involved in the establishment of the smear campaign reached out to me to respectfully discuss the science. As a result, I wrote, along with collaborators, a brief two-page 'guide' to provide some key scientific references. Here, I have assembled a much more comprehensive guide, written with the goal of trying to communicate complex scientific principles to a lay person, yet with sufficient scientific rigour to also address experts. As I have often done with presentations and articles over the past year, I have set up this guide to answer the most common questions that I have received from the public. It is with sincere concern, and with the best interests of my fellow Canadians in mind, that I present you with the information that follows.

The problem: COVID-19

"COVID-19" is a disease that develops in a subset of individuals infected with a virus that is known as 'severe acute respiratory syndrome-coronavirus-2' (SARS-CoV-2). In the vast majority of cases of SARS-CoV-2 infections, people remain healthy (*i.e.* they are 'asymptomatic') or develop only mild to moderate symptoms of illness. However, in some cases, severe, and potentially lethal pneumonia, occasionally accompanied by other inflammatory events causing bleeding, clotting and/or neurological impairment, can develop in people in high-risk demographics, which includes the frail elderly and individuals who are immunocompromised (*i.e.* their immune systems do not function properly). Many people who become infected with SARS-CoV-2 do not develop the disease called COVID-19.

What is 'herd immunity'?

The concept of 'herd immunity' means that a virus will stop spreading among a population once most of the people in that population acquire a protective immune response. Importantly, this does not require every person to become immune, just a large majority. There are two ways for people to acquire immunity to SARS-CoV-2 and thus avoid the debilitating effects of COVID-19:



1. Natural infection:

When infected with SARS-CoV-2, most people clear this virus from their body by mounting a robust, long-lasting immune response that targets multiple components of the virus[1]. These people will be protected from re-infection with the same variant of SARS-CoV-2 and, due to the breadth of a natural immune response, will also likely have some degree of protection against emerging new variants of SARS-CoV-2. Indeed, most people who have naturally acquired immunity should not be at risk of developing severe disease even if variants arise that can effectively bypass the narrower immunity conferred by COVID-19 vaccines that are focused on a single component of SARS-CoV-2, such as the spike protein[2]. Interestingly, a landmark study in Canada suggested that a majority of healthy adults in British Columbia have evidence of pre-existing or naturally acquired immunity to SARS-CoV-2[3].

2. Vaccination:

Vaccines that have undergone properly conducted preclinical studies and the full suite of clinical trials to ensure they are (i) effective; and (ii) have excellent short-term and long-term (*i.e.* a minimum of two years; preferably longer) safety profiles, can allow an individual to become immune to a virus without having to be naturally infected.

How do vaccines work?

A successful vaccine must provide two things:

Thing 1: The virus or a piece(s) of the virus (*i.e.* a target for the immune system).

Thing 2: A danger signal (*i.e.* something that tells the person's immune system that the target it is seeing is dangerous and, therefore, worth responding to).

An effective vaccine simulates just enough of a natural infection, to trigger a person's body to develop an appropriate immune response without causing disease. Then, when the person becomes infected the first time by the natural virus, their body's immune system senses it is seeing the virus for the second time. This is because an immune response triggered by successful vaccination involves the body's development of 'immunological memory'. Therefore, the person's vaccine-primed immune response to the natural viral exposure will be faster and more robust, and the virus will be cleared without the person experiencing disease. Mass vaccination can accelerate progress of a population towards herd immunity.

How do Canada's COVID-19 vaccines work?

Canada currently has four COVID-19 vaccines that Health Canada has "Authorized by Interim Order". The Interim Orders enable the widespread deployment of the vaccines while the Phase 3 clinical studies (experiments in people) are being conducted. In the Phase 3 studies, all vaccine recipients must be followed for two years following the administration of the second vaccine dose. As long-term effects of the vaccine have yet to be understood, the vaccine is largely investigational. This is why the authorizations are "interim" and continued use is contingent on the collection of additional data from the Phase 3 studies, as well as other surveillance systems to assess the safety and effectiveness of the vaccines. Because the COVID-19 vaccines are being administered in Canada under experimental trial conditions, people receiving these vaccines should provide informed consent prior to being immunized. Informed consent demands that people be provided with all the known pros and cons, in an objective fashion and without undue pressure or coercion. This is a basic tenet of bioethics. Anyone administering a COVID-19 vaccine should be able to explain the benefits and risks based on the weight of the evidence provided in peer-reviewed, published scientific papers. Lay persons are encouraged to ask public health officials to explain the rationale for any statements made regarding COVID-19 vaccines and to have the sources of this information identified. Numbers in printed documents that do not contain citations do not necessarily reflect the robustness of the scientific literature.

The four COVID-19 vaccines currently being used in Canada include:

1. AstraZeneca/COVISHIELD vaccine (ChAdOx1-S):

These are two different names for the same vaccine (COVISHIELD is the brand name of AstraZeneca's vaccine that is manufactured by Verity Pharmaceuticals Inc. with the Serum Institute of India). Developed by AstraZeneca and Oxford University, the backbone of this vaccine is an adenovirus that does not cause disease in people. This adenovirus virus carries genetic material that provides instructions for a cell to manufacture a piece of SARS-CoV-2 (*i.e.*, the spike protein). When this adenovirus-based vaccine gets injected into the shoulder muscle, it is intended to infect cells and use the 'machinery' in these cells to manufacture small amounts of the SARS-CoV-2 spike protein. The SARS-CoV-2 spike protein and the adenovirus backbone provide the 'thing 1' and 'thing 2', respectively, that are needed to trigger an immune response.

Unfortunately, the rollout of the AstraZeneca vaccine in Canada proved to be a frustrating and complicated series of ever-changing, safety-triggered, recommendations given to a growing number of confused and distrusting members of the public. While many other countries paused their AstraZeneca vaccination programs to investigate safety issues related to potentially fatal blood clots, Canadians were told the AstraZeneca vaccine was safe for some population segments

and vaccinations with the AstraZeneca vaccine were initiated. After other countries practiced due diligence and confirmed that blood clotting was an adverse event associated with this vaccine, Canadians were then told that it was too unsafe for those under 55 years of age. Then Canadians between 40-55 years of age were told it was safe enough for them to use. Several weeks later, the message changed again, and the current messaging is that it is too unsafe to use as a first does in much of Canada. Millions of Canadians who received a single dose of this vaccine have since been wondering what to do. This highlights why the scientific method exists and why it should not be over-ridden by zealous public health officials. Safety testing should never be cut short. In many parts of Canada, the AstraZeneca vaccine is generally being used only for second doses for individuals who have had a first dose of the AstraZeneca vaccine and do not wish to have a second dose of another vaccine. The vaccine is irrelevant to Canadian children, youth, and young adults of child-bearing age, as it was never authorized for use in these population groups.

2. Janssen vaccine (Ad26.COV2.S):

This vaccine is made by Johnson & Johnson. Like the AstraZeneca vaccine, the Johnson & Johnson vaccine uses an adenovirus, albeit a different one. The way this vaccine works is similar to the AstraZeneca vaccine. After injection, cells infected with the adenovirus start to manufacture a spike protein that is very similar to that of the SARS-CoV-2 spike protein. There has been some public acknowledgement that this vaccine might also be associated with blood clots, and Health Canada has noted in their website notices of April 26th 2021 to healthcare professionals that "[v]ery rare cases of thrombosis in combination with thrombocytopenia, in some cases accompanied by bleeding, have been observed following vaccination with Janssen COVID-19 vaccine. A causal relationship with the vaccine is considered plausible." In considering the request for the Janssen vaccine to be Authorized Under Interim Order, Health Canada yet again acknowledged that "[i]mportant limitations of the data at this time include the lack of information on the long-term safety and effectiveness of the vaccine, interactions with other vaccines, and the lack of data in sub-populations (*e.g.* pregnant/breastfeeding women, pediatric population <18 years of age, patients with autoimmune or inflammatory disorders, immunocompromised patients and frail patients with comorbidities)." At the timing of writing this article, this vaccine has not been authorized for use in Canadian children, youth, and young adults of child-bearing age.

3. Pfizer BioNTech vaccine (BNT162b2):

This vaccine relies on technology that, prior to the COVID-19 pandemic, was not previously used in humans, except in small-scale clinical trials (such as a clinical trial of a rabies mRNA vaccine)[4]. The backbone of the Pfizer BioNTech vaccine is a lipid nanoparticle (a small bubble of fat). Inside the nanoparticle is a 'messenger ribonucleic acid' (mRNA). This is a tiny piece of genetic material that provides the instructions for a cell to manufacture a modified version of the SARS-CoV-2 spike protein. When these nanoparticles are injected into the body, they are

intended to fuse with cells with which they come into contact. When this happens, the mRNA migrates from the lipid nanoparticle and into the cell and the cell 'machinery' then uses this mRNA 'blueprint' to manufacture the modified version of the SARS-CoV-2 spike protein. This protein is the 'thing 1' that provides one of the two signals required for the immune system to become activated. It is not entirely clear what provides 'thing 2'. However, mRNA vaccines promote inflammation that can cause injury to normal tissue. When cells are injured, they release 'danger signals'. This might be what is providing the second signal ('thing 2') needed to induce an immune response.

Pfizer's vaccine has been associated with anaphylactic reactions in a small subset of individuals. These are serious allergic reactions that can be life-threatening. At the time of writing this guide, **the Pfizer vaccine is the only one that has received Authorization under Interim Order for Canadian children and adolescents 12 to 15 years of age.** In its decision-making process, Health Canada declared; "Health Canada has conducted a rigorous scientific review of the available medical evidence to assess the safety of the Pfizer-BioNTech COVID-19 vaccine. No major safety concerns have been identified in the data that we reviewed" [emphasis added]. Health Canada also acknowledged that "One limitation of the data at this time is the lack of information on the long-term safety and efficacy of the vaccine. The identified limitations are managed through labelling and the Risk Management Plan. The Phase 3 Study is ongoing and will continue to collect information on the long-term safety and efficacy of the vaccine. There are post-authorization commitments for monitoring the long-term safety and efficacy of Pfizer-BioNTech COVID-19 vaccine." Specifically related to the authorization for adolescents 12 to 15 years of age, "Health Canada declared, Health Canada has placed terms and conditions on this authorization requiring Pfizer-BioNTech to continue providing information to Health Canada on the safety, efficacy and quality of the vaccine in this younger age group to ensure its benefits continue to be demonstrated once it is on the market."

4. Moderna vaccine (mRNA 1273 SARS-CoV-2):

The Moderna vaccine also is an mRNA-based vaccine and, therefore, works the same way as Pfizer's COVID-19 vaccine. This vaccine has also been associated with anaphylactic reactions in a small subset of individuals. On June 7th 2021, Moderna had filed an application to extend the Authorization under an Interim Order to adolescents aged 12 to 17 years. At the time of writing this guide, Health Canada had not issued its decision.

None of Canada's COVID-19 vaccines can, in and of themselves, infect people with the SARS-CoV-2 virus, per se. Rather, these vaccines trigger the cells in a person's own body to manufacture one of the proteins that is a component part of SARS-CoV-2, and all the vaccines cause a person to make a modified version of the spike protein from SARS-CoV-2. The AstraZeneca vaccine contains the manufacturing blueprint for the exact same spike protein as is found on SARS-CoV-2. In contrast, the other three vaccines in use in Canada contain the manufacturing blueprint for a modified version that scientists refer to as the 'prefusion-stabilized spike'. All four vaccines are

designed to use the body's internal capability to manufacture the spike protein to then trigger the body's immune response.

What are the known serious adverse events that are associated with COVID-19 vaccines?

Using the United States Vaccine Adverse Event Reporting System (U.S. VAERS), as of June 11th 2021, the 20 most frequently reported adverse events (presented in descending order) were headache, pyrexia (fever), fatigue, chills, pain, nausea, dizziness, pain in extremity, injection site pain, myalgia (muscle pain), injection site erythema (redness), arthralgia (joint stiffness), pruritus (itching), rash, dyspnoea (difficulty breathing), injection site swelling, injection site pruritus (itching), vomiting, and asthenia (weakness). These side effects are common side effects and are similar to those reported in the Phase 3 clinical trials. Although these symptoms can be severe in some people and can result in an inability to perform daily activities, they usually subside over one to three days.

The mRNA vaccines (Pfizer and Moderna) can, in rare cases, cause anaphylaxis. Since this can be potentially fatal, these vaccines are often administered in special vaccine clinics that are staffed with personnel trained to treat people who may experience anaphylactic shock. The reason this problem is thought to be limited to the mRNA vaccines is likely due to a pre-existing allergy against something present in the liposome nanoparticles (the small bubble of fat) that are the part of the vaccine that envelopes the mRNA material. One of the liposome ingredients that might be the culprit is polyethylene glycol (PEG).

Based on data from international regulatory agencies (such as the Norwegian Medicines Agency), the adenovirus-based vaccines (*i.e.* AstraZeneca and Janssen) have been implicated in causing a very serious type of blood clot (a cerebral venous sinus thrombosis) that is simultaneously associated with a low platelet count and bleeding following vaccination. This is one of the reasons the AstraZeneca vaccine has largely been suspended for use in Canada, with the exception of use for second doses in those who received the AstraZeneca as their first dose and wish to stay with the same vaccine brand.

Are there other serious adverse events associated with COVID-19 vaccines that are being investigated?

Side effects that are rarer, including those that are serious or life-threatening, are still being learned about. For example, the United States Centers for Disease Control and Prevention (CDC) announced, only on June 11th 2021, that an Emergency Meeting would be held on June 18th 2021 to discuss reports of inflammation of the heart resulting from use of the Pfizer and Moderna vaccines in young males 16 to 24 years of age. It has been approximately six months since the vaccines were authorized under an emergency use in the U.S., and only now is this

association being recognized. There are many reasons why it is difficult to identify serious side effects that are rare or that occur only over a longer period of time or in a specific population group or sex. These difficulties are described below.

Difficulty #1: Too Soon to Tell for Sure

Pfizer and Moderna each initiated large, Phase 3 trials that were randomized, double-blind, and placebo-controlled. The placebo group is important because it serves as the reference group and helps in the interpretation of side effects experienced in the vaccine group. At the time that the vaccines were granted emergency use authorization, each company had safety and efficacy data for an average of only two months following the administration of the second vaccine dose; in the study in adolescents, most subjects had safety and efficacy data for either one or two months. According to the original protocols, every individual in the study is supposed to be followed for a total of two years following their second dose.

Difficulty #2: Abandoning the Control Group

The vaccines have been authorized under emergency use in many key countries, globally; and fear-based pressures imposed by public health agencies to vaccinate everyone has triggered study participants to want to know which study group they had been allocated to, so that those in the placebo group could be vaccinated. The studies have therefore been unblinded, meaning there is no longer a placebo group. This means that a rigorous assessment of safety in the context of a well-controlled clinical study is no longer possible, and there must be increased reliance on vaccine post-deployment, passive surveillance systems. Of course, this, itself, is challenging, given that there is uncertainty in both the numerator (the number of vaccine-related adverse events) and the denominator (the number that is typical for that event, otherwise referred to as the "background incidence" of the event). Moreover, it is extremely difficult to prove definitively that an event is caused by (and not just associated with) vaccination when using passive surveillance systems.

Difficulty #3: Under-Reporting of Adverse Events

The problem with passive adverse event reporting systems, which is the type of system that both Canada and the U.S. are relying on, is that there is a notorious problem of adverse event under-reporting. This is because reporting is voluntary; people may be unaware there are ways to report adverse events; people are often discouraged from reporting adverse events; people (including attending physicians) assume the condition is not related to vaccination; or people may not be able to report their adverse events (if they are severely disabled, ill, or deceased). Most disconcerting is the situation, as we see in Canada, where adverse event reports attempted to be submitted by medical professionals are pre-screened and sometimes rejected by pre-screening authorities. Consequently, adverse event databases can easily fail to identify potential concerns, or underestimate problems to an unknown degree and are, therefore, not a source of

accurate numbers to calculate true risk. For example, using the U.S. VAERS, it was estimated that the risk of anaphylaxis was 4.7 per million for the Pfizer vaccine and 2.5 per million for the Moderna vaccine[5]; however, in an active surveillance study of 64,900 healthcare workers who had been vaccinated, the rate was actually 216 per million[5], representing a potential rate of under-reporting of 46- to 86-fold. Despite these limitations, passive surveillance systems are useful for identifying potential risks that could then be investigated in properly designed safety studies.

Difficulty #4: Lack of Global Consistency and Thoroughness in Defining Events of Special Interest

Using the U.S. VAERS and similar adverse event reporting systems around the world, there is continuous monitoring of adverse events of special interest. But each jurisdiction is left to their own discretion to decide which, if any, particular adverse events of special interest will receive closer scrutiny. For example, the European Medicines Agency has compiled a list of important medical events (IMEs) which are always to be classified as serious (the IME list). The IMEs that are most frequently reported following COVID-19 vaccination (in descending order) are:

- Fainting (syncope)
- Blood clot(s) in the lungs
- Anaphylactic reaction
- Deep vein thrombosis
- Pneumonia
- Low blood platelet count (thrombocytopenia)
- Blood clot(s) or bleeding in the brain
- Hallucinations
- Cerebral stroke
- Loss of consciousness

Definitive cause-and-effect relationships for these events have not yet been established; it is hoped that with additional surveillance and time, clarity on the role of the vaccines in the cause of these events will be better understood. In the meantime, given that the spike protein is biologically active and there are mechanisms that could potentially explain some of these IMEs (discussed further below), there is good reason for genuine concern.

Why weren't serious adverse events identified before vaccines were rolled out?

Problems like anaphylactic shock (a severe allergic reaction) and potentially fatal blood clots were not identified until most of the experimental COVID-19 vaccines were used widely among the public[5, 6]. Janssen's study of the Johnson & Johnson vaccine did suggest some propensity for blood clotting. As for anaphylactic reactions, people with a history of allergies were excluded from the earlier clinical trials.

Another reason why some problems were not identified earlier is because short-cuts were taken with the traditional approach to vaccine research. Specifically, **the time taken to assess safety was too short**. Instead of taking the usual ~4-10 years to undergo thorough *in vitro* (*i.e.*, benchtop) tests, pre-clinical (*i.e.*, animal) studies, and then sequential clinical testing (*i.e.*, human Phase 1, 2 and 3 trials), COVID-19 vaccines were developed and assessed for safety and efficacy in less than one year. This meant that only very short-term safety scenarios could be evaluated. Of equal concern, **the number of people that were evaluated in clinical trials was too small** to capture rare but dangerous side-effects. This is unfortunate, because we have seen in Canada that rare but serious problems can lead to a vaccine program being suspended. Indeed, in Canada, a risk of blood clots for the AstraZeneca vaccine of 1 out of every 55,000 people vaccinated was deemed to be too dangerous, leading to its use being halted. Authorization under Interim Order for COVID-19 vaccines was granted after they were evaluated for a short duration in about 20,000 people. This means these studies could, at best, detect serious side effects that would occur in at least 1 out of every 20,000 people. In other words, the study design included a test population that was too small to identify vaccines that may be too dangerous for Canadians.

A clinical trial was conducted to justify using the Pfizer vaccine in Canadian children and adolescents; was it flawed as well?

Yes. First, it was far too short in duration to have any chance of assessing anything other than short-term harm. Also, in light of the information provided above, one needs to consider the following: only 1,131 adolescents between the ages of 12 and 15 received the vaccine in this study. This means that the study would have only been able to detect a serious side effect that occurs in 1 out of every 1,131 adolescents that are vaccinated; but a 1 in 55,000 risk was deemed to be too dangerous for adults for whom SARS-CoV-2 represents a greater risk. Furthermore, based on the recent observation of increased risk of heart inflammation following immunization with either the Pfizer or Moderna vaccine in young males, it appears serious side effects may be a function of both age and sex. In this regard, the Pfizer study of only 1,131 subjects provides even less robust data...enough to detect a serious gender-differentiating side effect that occurs in one out of approximately 565 (*i.e.*, 1,131÷2) males vaccinated and one out of approximately 565 females vaccinated.

But we have been told that adolescents and children can: (a) die from COVID-19, (b) suffer severe disease, and (c) be asymptomatic spreaders of SARS-CoV-2 and, therefore, kill others. Don't these risks suggest that children, youth, and young adults of child-bearing age should be vaccinated?

No, they don't. Let's break this down...

(a) Deaths due to COVID-19 are extremely rare in young Canadians. In sixteen months 13 Canadians under the age of 20 have died of 266,852 with confirmed SARS-CoV-2 infection (data from the Government of Canada, as of June 11, 2021). Because many children have asymptomatic infections, the true denominator is likely greater. This loss of 13 lives is indeed a tragedy, but no more so than the ~2,266 Canadians under the age of 20 who die from other causes every 16 months. Basic cost-benefit analyses have been largely ignored during the pandemic. The fear of young people dying from SARS-CoV-2 has reached a point where we seem to have placed a much higher value on lives lost due to COVID-19 than lives lost to any other causes.

SARS-CoV-2 is not a problem of pandemic proportions for all demographics. Infection fatality rate (IFR) is a way to assess how dangerous a pathogen is. The IFR is calculated based on the number of people who die, from among the total number infected. Early in the declared COVID-19 pandemic, it was estimated that the IFR for SARS-CoV-2 was ~10-fold higher than for a serious outbreak of an influenza virus, or ~1%; maybe even as high as 10%. Indeed, the IFR for a bad 'flu' season can be as high as ~0.1%[7]. This IFR for influenza is calculated despite the high use of influenza vaccines that are commonly given seasonally to target populations. It is important to note that calculating an accurate IFR requires having accurate data for the denominator in the equation, which is the total number of people that have been infected.

Exacerbated by Canada's lack of testing for evidence of seroconversion (*i.e.* when virus-specific antibodies are present in an individual, which indicates they were infected) against SARS-CoV-2, it has been impossible to ascertain how many Canadians have been infected. However, as data have accumulated in countries that did practice due diligence in this area, the total number of infections that have occurred keeps getting re-adjusted to higher numbers. This is due to phenomena such as the large number of people who were infected but did not realize it, because they never became ill (they never developed COVID-19). As a result, the actual calculated IFR for SARS-CoV-2 has been steadily declining. Remarkably, as the data regarding total infections have become more accurate, the IFR for SARS-CoV-2 has most recently been estimated to be only ~0.15%[8]. It is likely that this IFR will drop even further as the extent of unnoticed infections is further elucidated.

Indeed, a recent study found that ~90% of randomly tested healthy adults in British Columbia had evidence of natural immunity to SARS-CoV-2[9]. This indicates that the denominator for determining the true IFR is likely substantially higher than previously appreciated, which would mean the IFR is less than 0.15%[9]. Further, this IFR includes the high-risk frail elderly, immunocompromised, smokers, highly obese people, and those with diabetes, pulmonary and cardiovascular disease. For Canadians who are outside of these high-risk demographics, the IFR would be much less than 0.15%, especially for children. Therefore, COVID-19 does not represent a substantial risk to children, youth, and young adults of child-bearing age[10].

(b) Very few children are at risk of developing severe COVID-19. It is challenging to know how small this risk is because public health officials have refused to differentiate the nature of the 'cases' of COVID-19 that have been reported. Many estimates of children in hospital with COVID-19 include children who were admitted for other reasons but had tested positive with SARS-CoV-2. The reality is that most cases in children and adolescents are mild. In fact, most children do not get sick at all after being infected with SARS-CoV-2. Children have a lower risk of developing disease, especially severe forms, compared to adults. This is in large part because they express in their lungs and airways lower concentrations of the "ACE2 receptor", a protein on the surface of various cells in the body that serves as a point of attachment for the SARS-CoV2 spike protein, and that when "docked" enables entry of the virus into the cell for subsequent replication and spread of infection.

(c) Asymptomatic transmission of SARS-CoV-2 is negligible. The definition of an asymptomatic individual is a person who is known to be infected with a microorganism but fails to develop symptoms associated with a disease. Indeed, we are all 'asymptomatic carriers' in the sense that we harbor trillions of bacteria and viruses in and on our bodies. However, these normal microbiomes usually do not cause us any disease, unless we become immunosuppressed or unless 'safe' microbes get transferred to anatomical locations where they can potentiate disease (*e.g.* fecal-to-oral transfer of some strains of *Escherichia coli*). So, in the context of SARS-CoV-2, an asymptomatic carrier would be defined as an individual who is infected with the virus but fails to develop COVID-19. A colleague of mine recently asked this rhetorical question: "didn't we previously call an asymptomatic person 'healthy'?"

A study of the prevalence of SARS-CoV-2 in ~10 million people in Wuhan, China found no evidence of asymptomatic transmission[11]. In the United Kingdom, the 'Scientific Advisory Group for Emergencies' recommended that "Prioritising rapid testing of symptomatic people is likely to have a greater impact on identifying positive cases and reducing transmission than frequent testing of asymptomatic people in an outbreak area"[12]. Consequently, they have asked their government to change their testing policy by moving away from asymptomatic testing. The World Health Organization notes that "Most PCR assays are indicated as an aid for diagnosis, therefore, health care providers must consider any result in combination with timing of sampling, specimen type, assay specifics, clinical observations, patient history, confirmed status of any contacts, and epidemiological information"[13].

On its own, a positive result on a PCR test to detect SARS-CoV-2 is insufficient to diagnose COVID-19, yet this has become routine in Canada. In addition to the potential for false positive tests, true positive results can also be obtained from genomes of SARS-CoV-2 particles that are no longer infectious. An example of the latter would be an individual who has mounted an effective immune response and may have remnant replication-incompetent viral particles or partially degraded viral genetic material. Indeed, following clearance of SARS-CoV-2 from the body, full and/or partial genomes of SARS-CoV-2 can remain for up to several weeks. One key reason for this is that some phagocytic cells, which are a component of the innate immune

system, can be long-lived. Phagocytosis, which is the engulfment and digestion of SARS-CoV-2, is a mechanism to kill and remove the virus from the body and to activate other white blood cells. As such, these can be a source of SARS-CoV-2 genetic material that could be amplified by a PCR test. However, this genetic material would not have the potential to cause COVID-19. Persistence of whole or partial genetic material that is not associated with infectious particles is well-documented for a variety of other viruses, including measles[14], Middle East Respiratory Syndrome (MERS)-coronavirus[15], and other coronaviruses[16].

Too often, a positive PCR test for the presence of SARS-CoV-2, is being used, on its own, to define positive cases of COVID-19. However, the presence of a portion of the viral genome in an individual, on its own, does not necessarily equate with disease (*i.e.* COVID-19). To be declared a COVID-19 "case", the infection would also have to be associated with expected signs such as antibody development and/or symptoms of disease. This is known as a clinical diagnosis and would be based on evaluation by a physician, in conjunction with test results. A gold-standard test for infectivity of a virus is a cell-based functional assay that determines the potential for the virus sample to cause cell death. However, such an assay is not in routine use in Canada. Absence of such an assay further confounds any meaningful interpretation of positive results in asymptomatic people. Drawing conclusions based solely on the results of laboratory tests, would take the diagnosis of diseases out of the hands of physicians, and place the onus for this on technicians employed by testing laboratories. Further confounding this issue is the fact that cases of COVID-19 can be claimed in the absence of confirming infection with SARS-CoV-2 (this is known as "ICD code U07.2 COVID-19, virus not identified")[17]. Worse, the definition of a case of COVID-19 has changed over time in Canada. Indeed, the government of Canada has stated the following on their website: "Previous versions of the COVID-19 case definition are available upon request. Please email COVID19Surveillance@canada.ca to request a copy or for more information."[17]

Positive PCR tests for SARS-CoV-2 in asymptomatic people are often based on what scientists call 'high cycle numbers' (also called "cycle thresholds" or Ct"). PCR tests that only yield a positive result at high cycle numbers brings into question whether or not these individuals actually harbor infectious viral particles. This, combined with the absence of a functional cell-based assay to prove infectivity, renders results of asymptomatic testing nearly impossible to interpret accurately. Indeed, the World Health Organization, agreeing with many health professionals around the world, has emphasized that spreading of SARS-CoV-2 by asymptomatic individuals is rare and an emphasis should be placed, therefore, on testing people with signs or symptoms of illness, not those who are apparently healthy[18]. Of particular concern is the high cycle numbers being used by labs in Ontario (*i.e.* up to 38 cycles being defined as 'positive' by Public Health Ontario[19]), to define a COVID-19 positive "case." Several studies have been conducted to determine the highest number of PCR cycles at which live SARS-CoV-2 from a sample could be successfully cultured in cells. These studies suggest that appropriate cycle thresholds were 25[20], 22-27[21], and 30[22] cycles. This indicates that tests with positive results obtained above 22-30 cycles are not clearly supportive of the presence of live (*i.e.* replication-competent) SARS-CoV-2. The logical conclusion is that it is erroneous to declare samples that test

positive at high cycle numbers, especially those above 30, as being "positive" for infectious SARS-CoV-2. Appendix 1 shows results of a published study that depicts the numbers of PCR cycles at which asymptomatic people tested positive for SARS-CoV-2 relative to that observed for people with symptomatic infections[23]. Remarkably, if the cut-off for positive test results was set to Ct values of 22 or 30 (*i.e.* the point beyond which samples fail to yield potentially infectious virus particles), the vast majority of 'positive test results' would be rendered negative. It was even concluded in a study by La Scola B, *et al.*, that patients testing 'positive' at cycle numbers above 33 could likely be discharged from hospitals[24]. This means that an unknown number of positive cases reported in Ontario were likely not true positives of COVID-19. This is further supported by evidence that asymptomatic people have detectable SARS-CoV-2-specific memory T immune cells after exposure to the virus, which would be inconsistent with a risk of them harboring and spreading the virus to others[25].

Importantly, false positive test results, which have a greater risk of happening among asymptomatic people, have been shown to have numerous negative consequences in terms of physical and mental health, and causes financial losses[26]. Testing of asymptomatic people for the presence of portions of the SARS-CoV-2 genome makes neither medical nor economic sense. Positive test results from asymptomatic individuals cannot be interpreted in a clinically meaningful way. Although asymptomatic transmission is theoretically possible, it is improbable that it is occurring in substantial numbers and does not represent a significant risk of causing COVID-19-related hospitalizations or deaths in others.

For all the aforementioned reasons, **it is wrong to label children as being asymptomatic spreaders of SARS-CoV-2** that will sicken and kill others. Indeed, as reported by L. T. Brandal *et al.*, "under 14 year olds are not the drivers of SARS-CoV-2 transmission"[27]. A study in England concluded "SARS-CoV-2 infections and outbreaks were uncommon in educational settings", with staff (adults), not students (children) being the primary source of infections[28].

Now that the reasons that were used to justify using an experimental COVID-19 vaccine in children have been put into a reasonable perspective, let's continue talking about the vaccine technology.

Why was the spike protein from SARS-CoV-2 chosen as a target for the immune system?

Electron micrograph of a coronavirus

The spike protein gives SARS-CoV-2 its 'crown-like' appearance, which means it looks like it has a 'corona'. This protein allows the virus to attach to our cells and then infect them. If antibodies can bind to and 'block' all the spike proteins on the surface of the virus, then it could not infect our cells. Moreover, the binding of antibodies to even a part of the virus can tag it for attack by cells of our immune system. As such, COVID-19

vaccines currently being used in Canada instruct our cells to manufacture the spike protein in order to trigger our bodies to mount an immune response against this protein with the hope that the ensuing antibodies will get into our lungs and airways and block the virus, should we be infected in the future.

What should we know about the SARS-CoV2 spike protein?

Before we go any further with the story about COVID-19 vaccines, there is important information that you need to know about the spike protein from SARS-CoV-2.

The spike protein from SARS-CoV-2 has the potential to damage cells in the body

In cases of severe COVID-19, problems can extend well beyond pneumonia and the associated inflammation in the lungs. The disease can progress beyond the lungs and into other parts of the body. In severe infections, SARS-CoV-2 can cause damage to the cardiovascular system (*i.e.* heart and blood vessels). In fact, some have referred to severe COVID-19 as largely being a vascular disease[29, 30, 31]. Blood clots, bleeding and/or damage to the heart have all been linked to severe COVID-19. Severe COVID-19 can also cause neurological problems (*i.e.* damage in the brain). A series of recent scientific publications provide some evidence that this damage throughout the body may not require an intact SARS-CoV-2 particle. Instead, the spike protein from SARS-CoV-2 might be responsible for at least some of the damage that occurs in severe cases of COVID-19[32]. This is because there are many cells other than those in the lungs and airways that feature the receptor for the spike protein, known as the ACE2 receptor. Most notably, platelets and cells lining blood vessels can express high concentrations of this receptor. Importantly, autopsies performed on patients who died from severe COVID-19 revealed that free spike protein from SARS-CoV-2, not the intact virus, was responsible for substantial damage throughout the body. Notably, blood vessels in the skin, fat, and the brain were found to express high concentrations of the ACE2 receptor that the spike protein binds to. There was a lot of spike protein found in these tissues, with little to no evidence of the intact virus being present. Indeed, the authors of the study that described these autopsies concluded "COVID-19 represents a viral infection with limited sites of infectious virions but deadly sequelae due to the effective manner in which pseudovirions in the context of released viral proteins activate synergistic microvascular pathways of tissue destruction throughout the body."[33] In lay language, proteins like the spike protein, not the intact virus, appear to mediate

much of the damage in the body in people who suffer from severe COVID-19. When the spike protein binds to these receptors, there are several events that can take place:

1. Proteins (called 'complement proteins') that are part of our innate immune system can get activated, causing inflammation that can damage or destroy the cells lining blood vessels and/or platelets[34]. Platelets that are required for clotting of blood also express ACE2 receptors that can bind with spike protein with dire consequences. Damage and destruction of platelets can cause their numbers to go down (a condition known as "thrombocytopenia"), and if platelet counts get too low and blood vessels are damaged, bleeding cannot be stopped. Therefore, the spike protein can potentiate bleeding.

2. Binding of the spike protein to platelets can also cause the platelets to become activated[35]. Activated platelets tend to clump, which can lead to the formation of clots. There is evidence that the spike protein can interact with other proteins in the blood to promote clotting[36]. As such, the spike protein can promote blood clotting.

3. Spike proteins binding to the cells that line our blood vessels can cause these cells to express proteins (known as 'caspases') that can cause the cells to die[33]. This is similar to findings from the 2002-2004 SARS outbreak where the spike protein from the original SARS-CoV could cause cells to die when it was being manufactured inside of them[37]. Dying cells that have been manufacturing the vaccine-encoded spike protein would release free spike protein or portions thereof.

4. Spike proteins binding to the cells that line our blood vessels can cause these cells to over-produce cell-signalling cytokines that can potentially contribute to dangerous 'cytokine storms' (overly robust and severe inflammation)[33, 38].

Of additional concern is the knowledge that the spike protein is capable of dissociating into two parts and these smaller subunits (S1 and S2) can cross the blood-brain barrier where they can potentially cause damage in the brain[39]. Indeed, people who have died from severe COVID-19 with neurological signs were found to have the spike proteins but not the intact virus in their brains[40]. These neurological signs could be seen in laboratory studies when spike proteins were injected into the blood of mice.

Conclusion: The spike protein, if it gets into circulation, has the potential to cause damage to the cardiovascular system and other tissues.

Back to the vaccines

Now that there is a clear understanding that the spike protein from SARS-CoV-2 is a dangerous toxin when it gets into the blood and is distributed throughout the body, we can continue with the story about COVID-19 vaccines.

Evidence that mRNA-based COVID-19 vaccines can get distributed throughout the body

When the COVID-19 vaccines were designed, it was not appreciated that the spike protein could potentially damage cells in the body. As a consequence, administration of the current COVID-19 vaccines can put people at risk of damaging their cells, especially if expression of the spike protein is not limited to the vaccine injection site. An assumption was made with these vaccines that has proven to be incorrect. The assumption was that mRNA vaccines, which are a new technology, would behave the same as traditional vaccines. It was thought by many that mRNA vaccines would stay at the injection site and the only other place they would go is to the draining lymph nodes in the immediate vicinity of the injection site. More specifically, it was thought that cells of the immune system would come to the site of injection and create pieces of the virus and take these pieces to the lymph nodes where they would be shown to B and T cells (*i.e.*, B and T lymphocytes). The B and T cells would then get activated, multiply to large numbers (this is why lymph nodes swell when a person is mounting an immune response) and then head out into the body to search for the pathogen. Notably, B cells are the source of antibodies. Unfortunately, researchers have come to learn that **the mRNA vaccines do not stay in the shoulder muscle**. In fact, **they have the potential to spread far and wide throughout the body via the blood**. Obviously, this is a very serious conclusion to draw, so let's walk through the solid scientific evidence that demonstrates this potential for biodistribution.

A report that Pfizer provided to the Japanese government (see Appendix 2) was published as reference #25 in an article[41] published in *BMJ* that can be found at this link. In section 2.6.5.5B of the report to the Japanese government there is a table containing lipid nanoparticle biodistribution data. This table shows where their surrogate "vaccine" (*i.e.* represented in the laboratory test by little bubbles of surrogate fat containing an analytical detection marker) ended up in the body of immunized rats, used in the laboratory as surrogates for humans. A portion of the table is reproduced below. Please review the data so you can get the full picture. I would like to highlight some observations. First, as shown in the blue rectangle that I added to the table, a lot of the surrogate vaccine dose remained at the injection site, as one would expect. Remarkably, however, most of the vaccine dose had gone elsewhere. The right side of the table (shown in the report to the Japanese government but not below) shows that 50-75% of the vaccine dose failed to remain the site of injection. The big question is, where did it go? Looking at the other tissues shows some of the places it went and accumulated. The red rectangle shows that **the surrogate vaccine was circulating in the blood**. There is also evidence that a substantial amount of the vaccine went to places like the spleen (green rectangle), liver (brown rectangle), ovaries (yellow

rectangle), adrenal glands (purple rectangle), and bone marrow (orange rectangle). The vaccine went to other places as well, such as testes, lungs, intestines, kidneys, thyroid gland, pituitary gland, uterus, *etc*. **The surrogate vaccine tested in a laboratory setting was widely distributed throughout the laboratory animals' bodies.**

Based on the results of this biodistribution test, further tests should have been required in order to assess the impacts on more tissues and for a longer time before the vaccine was authorized for use, especially in growing children, adolescents, and young adults of child-bearing age. The vaccine manufacturer, researchers and regulatory authorities alike should have also looked more comprehensively at the potential for the test animals to shed the vaccine by assessing saliva, urine, and feces. Note that there was evidence of some trafficking of the vaccine to the salivary gland and bladder, which indicates there is potential for some degree of shedding of the vaccine from the body. Further, the biodistribution of the spike protein that is created by the body after vaccination should be carefully mapped. Studies such as these should be performed in at least two animal models, with one of these not being a rodent model since rodents have levels of ACE2 receptor binding affinity that is far less than that of humans and may, as a result, underestimate the impact of spike protein on humans. There should also have been an evaluation of where the vaccine and the spike protein were going in humans in a very limited Phase 1 clinical safety trial. **This may not have mattered as much if the protein encoded by the mRNA was inert, although the risks of autoimmunity with the deposition of the lipid nanomaterials at different organs are certainly worthy of consideration. But now that we know the spike protein encoded by the mRNA has**

its own biological activities of concern, there is even greater potential for damage to organs and tissues arising from circulating vaccine material.

Although not as detailed as the data in the report to the Japanese government, Pfizer's report to the European Medicines Agency states similar findings regarding the broad distribution of their vaccine platform throughout the body. The report is in Appendix 3. Of great concern is the following excerpt from section 2.3.2 on page 45: "**No traditional pharmacokinetic or biodistribution studies have been performed with the [Pfizer-BioNTech] vaccine candidate BNT162b2**". If this is the first time this vaccine technology platform has been rolled out for wide distribution to humans, and if the Japanese biodistribution data showed evidence of spread of the surrogate vaccine material, one must ask **why was this experimental vaccine allowed to be used in people without it having undergone a crucial biodistribution study first?** This would have told us where the vaccine was going in the body before its use in people.

Supporting the need to address uncertainties and concerns regarding the biodistribution of the vaccine and the resulting spike protein is a peer-reviewed scientific paper that has just been accepted for publication. It describes a study in which 13 healthcare workers were assessed for the presence of the spike protein in their blood after receiving Moderna's vaccine (an mRNA vaccine with essentially identical platform technology as the Pfizer-BioNTech vaccine). Notably, the spike protein, (or the portion of it that binds to ACE2 receptor), could be found in the circulation in 3 out of the 13 people (and in 11 out of the 13 people), respectively[42]. The spike protein could be detected in the blood up to two weeks post-vaccination in most individuals and at 28 days post-vaccination in one individual. Some may argue that the concentration of the protein was low in most of the people studied. However, a protein circulating at a low concentration for up to two or more weeks could accumulate on cells over time as the blood constantly perfuses *(i.e.*, flows through) bodily tissues. Further, the biodistribution studies in the appendices suggest the spike protein could potentially be concentrated in many tissues that would not be evident by looking in blood alone. The possibility also exists that there were spike proteins already bound to ACE2 on the cells lining the blood vessels, but this was not investigated. Regardless, low concentrations of the spike protein in circulation would be expected in this small-scale study. High concentrations of a protein that can cause damage to blood vessels in a large number of people would not be consistent with a low incidence of severe adverse events. Remember, the AstraZeneca vaccination program was suspended in Canada due to a 1:55,000 incidence of blood clots. If spike proteins in blood were responsible for a severe side-effect, one would expect to see high concentrations of this protein in only one out of many thousands of people; a phenomenon that would likely not be detected in an analysis of only 13 people. Clearly, more work is needed here to assess the biodistribution of spike proteins in the human body after vaccination.

In a pre-print article (note: this means the paper has not yet undergone independent scientific peer review), there are data that indicate mRNA can even be detected in breast milk post-vaccination. This aspect of the study was downplayed but provides proof-of-principle that

this can happen. Knowing what we now know, it would not be surprising to have the spike protein in the breast milk of some lactating women if they were to be vaccinated. Proteins circulating in the blood usually get concentrated in breast milk. Notably, there have been some adverse events reported of infants experiencing bleeding in their gastrointestinal tracts after suckling from mothers who had received a COVID-19 vaccine. Here are some examples from the U.S. VAERS (I haven't checked for more since May 2021):

Serious Adverse Events Related to Breastfeeding After Receiving a COVID-19 Vaccine

- VAERS ID #945282; a 32-year-old mother had her 2-month-old breastfeeding daughter die 7 days after the mother had received the Pfizer-BioNTech vaccine
- VAERS ID #949926; a 34-year-old mother had her 4-month-old breastfeeding boy pass blood and mucous in the stools starting 2 days after the mother had received the Moderna vaccine
- VAERS ID #992676; a 30-year-old mother had her 2-month-old breastfeeding boy experience anorexia, spitting up, discoloured bloody feces, vomiting of blood, ulceration of the stomach, and bleeding in the gastrointestinal tract starting 2 days after the mother had received the Moderna vaccine

There were also other types of adverse events in infants associated with breastfeeding from mothers who had recently received a COVID-19 vaccine. For the sake of brevity, I have listed the VAERS ID #s here; anyone can look them up in the publicly available VAERS database.

- VAERS ID #s: 903355, 911226, 913968, 913971, 918972, 921052, 927664, 936865, 939409, 974519, 978085, 978485, 984448 (mother) - 984602 (infant), 1049482, 1105816, 1168901, 1171284

There is also a pre-print article that describes how an adenovirus-based vaccine can result in spike proteins damaging the vascular system. These types of vaccines are currently not being given to children in Canada. The mechanism is different from the mRNA-based vaccines, but the outcome is similar. The authors of this paper have coined an interesting term to describe the effect of a COVID-19 vaccine causing the same damage to the body that SARS-CoV-2 does; they called it "vaccine-induced COVID-19 mimicry syndrome".

It turns out that the suggested wide distribution of mRNA vaccines throughout the body has a historical precedent, such as for immunizing against influenza for example[43]. However, many people do not realize that lipid nanoparticles were not designed to function as vaccines. They were designed to serve as gene therapies or carry drug cargo throughout the body[44], including into the brain where attempts could be made to treat diseases such as Alzheimer's disease, Parkinson's disease, and brain cancers. Of substantial concern is the use of PEG, which has been associated with anaphylactic shock in some people after receiving a mRNA vaccine. PEG was added to lipid nanoparticles in the early days of drug development to promote much wider distribution throughout the body. Specifically, when PEG is added to lipid nanoparticles, it helps

the particles avoid being consumed by cells throughout the body, especially cells of the immune system, that would limit the distribution of the mRNA cargo[45, 46]. Indeed, addition of PEG to lipid nanoparticles was hailed as a breakthrough because "This effect is substantially greater than that observed previously with conventional liposomes and is associated with a more than 5-fold prolongation of liposome circulation time in blood"[45]. In retrospect, it seems that another mistake may have been made in the rush to get these vaccines into people: Arguably, the PEG component should have been removed from the lipid nanoparticle formulation. This likely would have resulted in lipid nanoparticles with a greater tendency to remain at the injection site and be picked up by the very cells of the immune system that we want to induce an immune response.

Conclusion: The assumption that COVID-19 vaccines remain at the injection site (*i.e.* the shoulder muscle) is not borne by the evidence. Laboratory studies have shown that the vaccine itself, and the spike protein that it encodes, may get into the blood, and be distributed widely throughout the body. Vaccines targeting the spike protein from SARS-CoV-2 were designed to induce antibodies that would bind to this protein to prevent the virus from being able to infect our bodies. The spike protein was supposed to be the 'first thing' that a vaccine must provide; a target for the immune system. We did not appreciate the potential for the spike protein alone to cause damage to cells in the body. We now understand that the current COVID-19 mRNA vaccines have the potential to be distributed throughout the body, thereby potentially and inadvertently inoculating many tissues with a protein that is possibly harmful. If unknown damage is being caused in some organs, this might not be clearly evident until years after vaccination. The data presented here do not provide proof of long-term harm. However, it provides the rationale for asking a number of safety questions. These questions should be thoroughly investigated in safety studies prior to using COVID-19 vaccines in children, adolescents, and young adults of child-bearing age.

A concern beyond circulating spike proteins: the potential for induction of autoimmunity

Some scientists have proposed that the spike protein from SARS-CoV-2 might have portions that are very similar to proteins in our own bodies[47]. If true, inducing immunity against the spike protein could theoretically promote autoimmune disorders. Indeed, two researchers found there was cross-reactivity between antibodies induced against the spike protein and several 'self' proteins[48]. This led to the recommendation almost one year ago to avoid targeting the entire spike protein in vaccines and instead target only portions of the protein that are not

similar to proteins in our own bodies. Unfortunately, autoimmune diseases can be insidious and take years for symptoms to become apparent.

The broad distribution of an mRNA vaccine throughout the body implicates other mechanisms that could lead to autoimmune disease. First, the mRNA vaccines promote robust inflammation. This is why many people have sore shoulders after being immunized. Promotion of inflammation in critical tissues, such as the ovaries, after being seeded with the vaccine could have dire consequences. Tissues like the ovaries are not supposed to become inflamed. This is because inflammation causes a lot of bystander damage to normal tissues, which is unwanted in an organ designed for reproduction. Also, the vaccine-encoded spike protein is designed to remain anchored on the surface of the cell that has manufactured it. If antibodies are present, such as would be the case several days after vaccination or natural infection, they could bind to the spike proteins on cells throughout our body, resulting in their destruction. Let's take the ovaries, again, as a theoretical scenario. If they were to undergo any type of tissue destruction, there is the possibility of proteins being released that the immune system has never seen before. This is because our immune systems learn to tolerate 'self' at a very young age. However, organs like the ovaries and testes start to express new proteins during puberty that the immune system has not been tolerized against. If these get released due to tissue damage, this could provide the same two signals that a vaccine needs to activate the immune system; signal 1 (target protein) and signal 2 (damage-associated danger signals). This could result in an autoimmune response against the organ. In this example (ovaries), such damage might not become apparent until years later when attempting to have a baby. This is speculation but is based on a huge body of scientific literature looking at how autoimmune diseases get started. Notably, this could potentially happen in any of the tissues seeded with the vaccine if they start to express the spike protein. This is certainly worthy of investigation before the mass vaccination of children, adolescents, and young adults of child-bearing age.

Even the fact that the current COVID-19 vaccines cause muscle cells in the shoulder to express the spike protein, is a potential problem. This could potentially result in immune responses being mounted against muscle tissue. This is of particular concern, because Israel has started to suspect a link between COVID-19 vaccines and inflammation in the heart muscle (a condition known as myocarditis). Indeed, this potential link is being actively investigated by the European Medicines Agency, as well as by the U.S. CDC. Again, with these kinds of concerns being raised in the global community, one must wonder why these vaccines are pushed so hard upon Canadian youth who are not at high risk of severe COVID-19. It will be a tragedy if we repeat something similar to or even worse than the AstraZeneca vaccine fiasco with our young people.

Why doesn't everyone who gets vaccinated experience a severe side-effect?

The spike protein likely does not get into circulation in every person. Indeed, in the study of 13 people vaccinated with the Moderna vaccine, ten had no evidence of the spike protein and

two had no evidence of the S1 subunit (a fragment of the spike protein) in their blood[42]. Also, it is important to remember that following vaccination, people manufacture the spike protein in their own cells. The amount and quality of mRNA in each dose of the vaccine can vary from batch to batch. The stability of the mRNA is also dependent on its handling as it is very temperature sensitive. So different people will receive different amounts of the active mRNA. People that receive the same amount of mRNA can produce different amounts of the spike protein depending on how metabolically active their cells are. And there are likely numerous other factors, including body size, *etc.* All of this could contribute to substantial variability in the concentration of spike proteins that a person produces. Notably, a standard vaccine injection might be expected to have a different impact in a 75-pound youth than in a 200-pound adult. The adverse events that we know about seem relatively rare. Some adverse events may go undetected. For example, knowing that the spike protein gets into circulation and knowing that it can kill platelets, it would not be surprising if most people have some loss of platelets after getting vaccinated. Also, platelets could pick up the mRNA from the circulating lipid nanoparticles and then display the spike protein on their surface, which would tag them for destruction by the ensuing antibody response. However, platelet counts are not being routinely monitored after people leave vaccination clinics, nor have the vaccine companies publicly released their data showing platelet counts post-immunization. Indeed, in a first-in-human study of BNT162b1, an earlier prototype of the Pfizer BioNTech BNT162b2 vaccine in use today, that encoded the S1 subunit of the spike protein (which contains the portion of the spike protein that binds to ACE2 receptors, called the receptor binding domain), platelet numbers dropped following vaccination in both the young and older adults studied[49]. Unfortunately, clinical chemistry and haematology values following vaccination with the BNT162b2 vaccine, which is the one currently being used to vaccinate people, were not published in Pfizer's first-in-human study[50].

One would be unaware if they were experiencing a loss of platelets unless their platelet count became dangerously low and they suffered trauma that would cause bleeding. Of greater concern is the potential for serious adverse events that we may not know about for quite some time. For example, damage to the ovaries or testicles might result in infertility that would not become apparent until attempting to have children. The oocytes that are present in the ovaries of newborn baby girls represent that female's life-long fixed supply of oocytes, which are the precursor of eggs. These oocytes cannot reproduce or regenerate if damaged or destroyed. Damage to the uterus could potentiate spontaneous abortions or miscarriages during pregnancy. The fact is, there is a clearly established set of biological mechanisms that raise numerous legitimate scientific concerns about COVID-19 vaccines. **We can't simply hope that none of these concerns end up being realized.** Instead, we must return to following the scientific method. We should stop the roll-out of the vaccination program for children, youth and young adults of child-bearing age, and ask the manufacturers of COVID-19 vaccines to take the time to conduct the proper biodistribution and safety studies to answer these emerging questions, and then conduct an accurate re-evaluation of the risk of COVID-19 versus the risks associated with the experimental COVID-19 vaccines.

Is the Pfizer BioNTech vaccine losing its effectiveness?

The stated purpose of vaccinating children, youth, and young adults of child-bearing age is to protect them from infection and reduce the risk of them transmitting SARS-CoV-2 to older adults. Therefore, it is important to note that the current COVID-19 vaccines fail to induce what we call 'sterilizing immunity'. This means that vaccinated individuals can still get infected with SARS-CoV-2, potentially become ill, and potentially transmit the virus to others. This is why vaccinated individuals are not exempt from lockdown policies and are still encouraged to wear masks. Importantly, there is evidence that the 'Delta variant' of SARS-CoV-2 has changed enough to be able to start evading the immunity conferred by the Pfizer BioNTech vaccine[51]. Indeed, the earlier 'South African' variant rendered AstraZeneca's vaccine only 10% effective[52]. With new variants on the horizon that will almost inevitably be able to bypass vaccine-induced immunity, this raises another question about whether the potential risks associated with the current vaccines are worth the minimal protection they will confer in the long-term to children, youth, and young adults of child-bearing age.

The Pfizer BioNTech vaccine might cause an excessive number of serious side-effects in young Canadians

As noted previously, Pfizer conducted an extremely small and very short-term clinical trial to test their vaccine in adolescents between the ages of 12-15 years. The results were reported in a fact sheet to the U.S. Food and Drug Administration. In this document, Pfizer defined severe adverse events as follows:

- Death
- A life-threatening adverse event
- Inpatient hospitalization or prolongation of existing hospitalization
- A persistent or significant incapacity or substantial disruption of the ability to conduct normal life functions
- A congenital anomaly/birth defect
- An important medical event that based on appropriate medical judgement may jeopardize the individual and may require medical or surgical intervention to prevent one of the outcomes listed above

No deaths occurred in this small study, but Pfizer did note the following on page 27 of their fact sheet: "Serious adverse events from Dose 1 through up to 30 days after Dose 2 in ongoing follow-up were reported by 0.4% of Pfizer-BioNTech COVID-19 Vaccine recipients and by 0.1% of placebo recipients." Much larger numbers of adolescents would have to be studied to provide conclusive evidence, but these limited data suggest the risk of serious adverse events

may have been 0.3% higher in the vaccinated group (not statistically significant in this small study).

As discussed previously, adverse events of special interest are being monitored, although the thoroughness is questionable, and the transparency of such activity is spotty at best. For example, the European Medicines Agency has compiled a list of important medical events (IMEs) which are always to be classified as serious (the IME list). The IMEs that are most frequently reported following COVID-19 vaccination include (in descending order):

- Fainting (syncope)
- Blood clot in the lungs
- Anaphylactic reaction
- Deep vein thrombosis
- Pneumonia
- Low blood platelet count (thrombocytopenia)
- Blood clots or bleeding in the brain
- Hallucinations
- Cerebral stroke
- Loss of consciousness

As the number of adolescents studied in the Pfizer trial was so small, it remains unclear whether adolescents also will experience these IMEs. It is not appropriate or ethical to experiment with youth, especially when their risk of severe COVID-19 is so low.

A side note about blood donations

Although not directly related to vaccinating children, adolescents, and young adults of child-bearing age, it is important to recognize that if the spike protein, which can cause substantial damage, gets into the blood after vaccination, this could have implications for donating blood. It would be unwise to infuse a blood product into a potentially fragile patient if it is contaminated with the spike protein. Worse, Pfizer's own biodistribution data demonstrate that the vaccine itself, not the spike protein, circulates in blood for at least two days post-immunization. Intravenous infusion of mRNA that can produce the spike protein in cells of the recipient should not be infused into patients who require blood. Remember, not only is there a risk of free-floating and cell-expressed spike proteins, but the lipid nanoparticles themselves can promote anaphylactic shock in a small subset of people. Of concern, Canadian Blood Services currently states their approval for receiving blood donations from people who have received a COVID-19 vaccine, without deferral. This is based on assumptions made using traditional vaccines that remain at the injection site, not novel mRNA-based vaccines that have been shown in laboratory studies to travel throughout the body. **This practice should be halted immediately** until it can be determined how long it takes for the lipid nanoparticles, and spike proteins to disappear from the blood. Canadian Blood Services should then recommend deferring blood

donations from vaccinated individuals until there is no risk of transferring lipid nanoparticles, mRNA, or spike proteins. The small-scale study that has looked at circulating levels of spike proteins suggests that it might not be safe to use blood products from a vaccinated individual for at least 4-5 weeks post-immunization[42]. In the United Kingdom, the National Health Service Blood and Transplant has recommended that, "COVID-19 vaccine – please wait 7 full days from your vaccine before donating on the 8th day. If you had side effects from the vaccine such as headache, temperature, aches, and chills, please wait 28 days from your recovery". It is unfortunate that there is not international collaboration with regards to recommendations for the donation of blood after COVID-19 vaccination.

What options are we left with if we pause the vaccination roll-out for children, adolescents, and young adults of child-bearing age?

Canada abandoned the original goal of learning to live with SARS-CoV-2 after the initial 2-3-week 'flattening of the curve' of daily cases of COVID-19 early in the year 2020. A massive amount of scientific data about COVID-19 has been compiled over the past 16 months. But we have not been following the accumulating science. It can direct us towards what one of my colleagues likes to call a 'rapid but soft landing.' The purpose of this guide was not to build a detailed exit strategy. However, I have also been closely following the scientific literature about strategies that can be used to effectively treat COVID-19, especially if they are implemented as an early out-patient, at-home treatment before the disease progresses to a level requiring hospitalization. Some, but all too few Canadian physicians, are aware of, or using, these early at-home treatment protocols. These protocols include safe and highly effective drugs like ivermectin, fluvoxamine, budesonide, zinc, melatonin, vitamin C, vitamin D, and many others. Several cocktails of approved drugs have proven to be particularly effective and are described in a variety of websites including TreatEarly.org, c19protocols.com, and FLCCC.net. There is now an avalanche of scientific data in support of these treatment options, but this digresses into an area beyond the scope of this guide. Unfortunately, the use of these effective therapies has never been promoted in Canada even though they could have prevented a lot of sickness and deaths and would have reduced the burden on intensive care units. Many people do not realize that the Interim Order or emergency use authorization of COVID-19 vaccines would have been contraindicated if there was acknowledgement of effective treatment strategies. This rule is in place to protect Canadians from being experimented on when there are viable alternatives that are known to be safe. However, it is never too late to do the right thing. Canada panicked and threw out pandemic preparedness plans at all its public institutions. Sometimes poor decisions occur when being made during a crisis and in the absence of established guidelines. It is time to move on. By promoting widespread use of effective treatments for COVID-19, Canada can safely narrow its experimental vaccination program and call for the science to catch up before subjecting our children, adolescents, and young adults of child-bearing age to potential harm.

Concluding remarks

Looking back through this report, it is clear that there are too many warning signals to ignore. Each individual signal may present a particular level of uncertainty, but when all the signals are considered together, the alert is deafening and must not be ignored. We must halt the vaccination of our children, adolescents, and young adults of child-bearing age. This can be done safely and expeditiously because:

- The risk of severe and potentially lethal COVID-19 in these specific populations is so low that we need to be very certain that risks associated with mass vaccination are not higher;
- Asymptomatic members of this population are not a substantial risk for passing COVID-19 to others; and
- There are effective early-treatment strategies and considerations for the very few children, adolescents, and young adults of child-bearing age who may be at risk of developing severe COVID-19.

Our younger generations of Canadians are our treasures and our future. Let's not put their futures at unnecessary risk by forcing upon them experimental vaccines that present newly identified and still-to-be-clarified dangers. Proof-of-principle now exists to demonstrate the current crop of vaccines may be dangerous. This risk, no matter how theoretical, must be further investigated and all concerns put to rest prior to the vaccination of our youth. It's time to sort out the science and reduce the pressures on parents and their children so they can make truly informed decisions. It is time to pass the torch from the pharmaceutical companies and hand it to the leaders and innovators among our community of physicians and researchers who have the skills, knowledge and experience to optimize excellent treatment strategies encompassing repurposed drugs that can be deployed to reduce the future casualties of this war against COVID-19.

What to do next?

If interested in obtaining more information relevant to COVID-19, please go to the Canadian COVID Care Alliance (CCCA) website at https://www.canadiancovidcarealliance.org/. There is an option to join an e-mail list if you are interested in receiving news from the CCCA.

An example of the expertise represented within CCCA's membership and their balanced scientific messaging with an emphasis on charting a safe but rapid exit from the cycles of lockdowns can be found here: https://trialsitenews.com/covid-19-expert-panel-the-path-forward-for-canadians-trialsite-webinar/. This discussion panel was set-up after the governments of Alberta, Saskatchewan, and Ontario failed to respond to invitations to engage scientists and physicians in respectful public discussions of the scientific knowledge that has accumulated about COVID-19.

Interviews that include one of the original inventors of mRNA vaccine technology (Dr. Robert Malone) opining on findings described in this guide can be found here and here.

Appendix 1

Most 'positive' results for the SARS-CoV-2 PCR test are negative based on the gold standard virology assay. Shown are graphs from Figure 2 of a paper published in the *Journal of the American Medical Association* (*JAMA Intern Med.* 2020; 180(11): 1447-1452. doi:10.1001/jamainternmed.2020.3862). The argument being made was that the frequency at which asymptomatic people tested positive for SARS-CoV-2 was like that observed for people with symptomatic infections. However, new cut-offs for a positive test result were placed at 22 (orange line) and 30 (red line) PCR cycles. These are the limits (depending on the laboratory) at which replication-competent SARS-CoV-2 can no longer be recovered from samples according to the gold standard functional virology assay. When this is done, it is apparent that most of the results would be negative (*i.e.* these samples would fail to transmit infectious SARS-CoV-2).

1. まとめ

BNT162b2（BioNTech コード番号：BNT162，Pfizer コード番号：PF-07302048）は，重症急性呼吸器症候群コロナウイルス 2（SARS-CoV-2）のスパイク糖タンパク質（S タンパク質）全長体をコードする修飾ヌクレオシド mRNA（modRNA）であり，SARS-CoV-2 による感染症に対する mRNA ワクチンの本質として開発が進められている。BNT162b2 の製剤化にあたっては，2 つの機能脂質である ALC-0315（アミノ脂質）および ALC-0159（PEG 脂質）ならびに 2 つの構造脂質として DSPC（1,2-distearoyl-sn-glycero-3-phosphocholine）およびコレステロールと混合することで BNT162b2 を封入する脂質ナノ粒子（LNP）が形成される（以降，「BNT162b2 封入 LNP」）。

BNT162b2 封入 LNP の非臨床薬物動態を評価するために，LNP に含まれる ALC-0315 および ALC-0159 の吸収（PK），代謝および排泄を評価する in vivo および in vitro 試験ならびに BNT162b2 の代替レポーターとしてルシフェラーゼまたは放射能標識した脂質を利用した生体内分布試験を実施した。

感染症予防を目的としたワクチンの開発では全身曝露量の評価を必要としないことを踏まえ（WHO, 2005；感染症予防ワクチンの非臨床試験ガイドライン）[1,2]，BNT162b2 封入 LNP の筋肉内投与による PK 試験は実施しなかった。また，本剤に含有される他の 2 種類の脂質（コレステロールおよび DSPC）は天然に存在する脂質であり，内在性脂質と同様に代謝，排泄されると考えられる。加えて，BNT162b2 は取り込んだ細胞中のリボヌクレアーゼにより分解されて核酸代謝され，BNT162b2 由来の S タンパク質はタンパク分解を受けると予想される。以上のことから，あらためてこれらの成分の代謝および排泄を評価する必要はないと考えられた。

BNT162b2 の代替レポーターとしてルシフェラーゼをコードする RNA を封入した LNP（ルシフェラーゼ RNA を BNT162b2 封入 LNP と同一の脂質構成を持つ LNP に封入：以降，「ルシフェラーゼ RNA 封入 LNP」）を Wistar Han ラットに静脈内投与した PK 試験では，血漿，尿，糞および肝臓試料を経時的に採取して，各試料中の ALC-0315 および ALC-0159 濃度を測定した。その結果，ALC-0315 および ALC-0159 は血中から肝臓にすみやかに分布することが示された。また，ALC-0315 および ALC-0159 はそれぞれ投与量の約 1%および約 50%が未変化体として糞中に排泄され，尿中においてはいずれも検出限界未満であった。

生体内分布試験では，ルシフェラーゼ RNA 封入 LNP を BALB/c マウスに筋肉内投与した。その結果，ルシフェラーゼの発現が投与部位でみられ，それより発現量は低値であったものの肝臓でも認められた。ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現も投与後 6 時間に認められ，投与後 48 時間までに消失した。また，ルシフェラーゼ RNA 封入 LNP の放射能標識体をラットに筋肉内投与して生体内分布を定量的に評価したところ，放射能濃度は投与部位で最も高値であった。投与部位以外では肝臓が最も高かった（投与量の最大 18%）。

ALC-0315 および ALC-0159 の代謝を CD-1/ICR マウス，Wistar Han または Sprague Dawley ラット，カニクイザルもしくはヒトの血液，肝ミクロソーム，肝 S9 画分および肝細胞を用いて in vitro で評価した。また，上記のラット静脈内投与 PK 試験で採取した血漿，尿，糞および肝臓試料を用いて in vivo 代謝についても検討した。これら in vitro および in vivo 試験から，ALC-0315 および ALC-0159 は，試験したいずれの動物種でも，それぞれエステル結合およびアミド結合の加水分解により緩徐に代謝されることが示された。

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

以上の非臨床薬物動態評価より，循環血中に到達した LNP は肝臓に分布することが示された。また，ALC-0315 および ALC-0159 の消失には，それぞれ代謝および糞中排泄が関与することが示唆された。

2. 分析法

報告書番号：PF-07302048_06[redacted]_072424

GLP 非適用のラット静脈内投与 PK 試験（M2.6.4.3 項）で LNP の構成脂質である ALC-0315 および ALC-0159 濃度を定量するために適切な性能を有する LC/MS 法を開発した。すなわち，20 µL の血漿，肝ホモジネート（肝臓の 3 箇所から採取した切片を用いてホモジネートを調製し，それらをプールしたものを適宜，ブランクマトリクスで希釈），尿および糞ホモジネート（適宜，ブランクマトリクスで希釈）試料をそれぞれ内部標準物質（PEG-2000）を含有するアセトニトリルで除タンパクした後，遠心分離し，その上清を LC-MS/MS 測定に供した。

3. 吸収

報告書番号：PF-07302048_06[redacted]_072424，概要表：2.6.5.3

ALC-0315 および ALC-0159 の体内動態を検討するため，ルシフェラーゼ RNA 封入 LNP を雄性 Wistar Han ラットに 1 mg RNA/kg の用量で単回静脈内投与し，経時的（投与前，投与後 0.1，0.25，0.5，1，3，6 および 24 時間ならびに投与後 2，4，8 および 14 日）に血漿および肝臓をスパースサンプリングにより採取（3 匹/時点）した。血漿中および肝臓中の ALC-0315 および ALC-0159 濃度を測定し，PK パラメータを算出した（Table 1）。血中の ALC-0315 および ALC-0159 は，投与後 24 時間までにすみやかに肝臓へ分布した。また，投与後 24 時間の血漿中濃度は最高血漿中濃度の 1%未満であった（Figure 1）。見かけの終末相消失半減期（t½）は血漿中および肝臓中で同程度で，ALC-0315 は 6～8 日，ALC-0159 は 2～3 日であった。本試験の結果から，肝臓が血中からの ALC-0315 および ALC-0159 を取り込む主要組織の 1 つであることが示唆された。

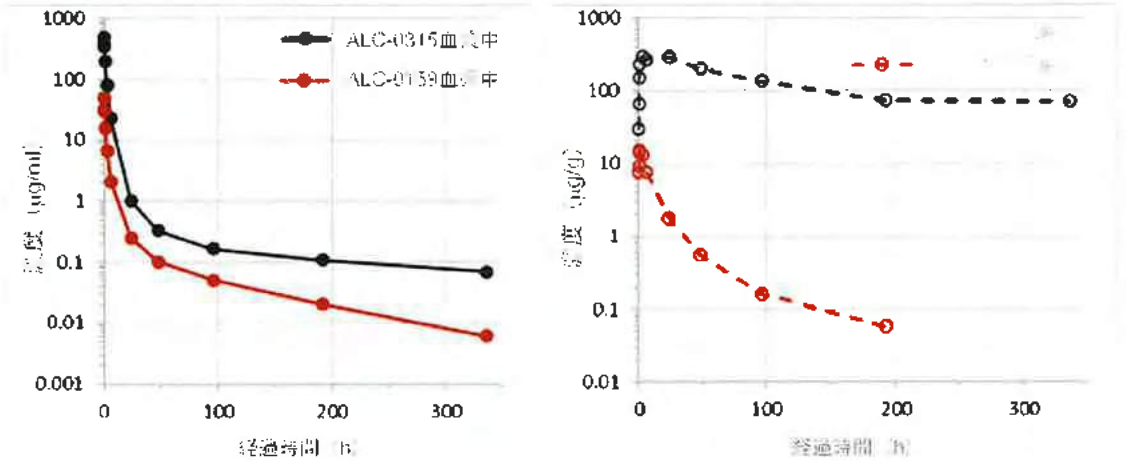
本試験において実施した ALC-0315 および ALC-0159 の尿中および糞中濃度の検討結果については M2.6.4.6 項で述べる。

Table 1 ルシフェラーゼ RNA 封入 LNP を Wistar Han ラットに 1 mg RNA/kg の用量で静脈内投与したときの ALC-0315 および ALC-0159 の薬物動態

分析物	分析物の投与量 (mg/kg)	性/N	t½ (h)	AUC_{inf} (µg•h/mL)	AUC_{last} (µg•h/mL)	肝臓への分布割合 (%)[a]
ALC-0315	15.3	雄/3[b]	139	1030	1020	60
ALC-0159	1.96	雄/3[b]	72.7	99.2	98.6	20

a. ［最高肝臓分布量 (µg)］/［投与量 (µg)］として算出。
b. 各時点 3 匹。スパースサンプリング。

Figure 1 ルシフェラーゼ RNA 封入 LNP を Wistar Han ラットに 1 mg RNA/kg の用量で静脈内投与したときの ALC-0315 および ALC-0159 の血漿および肝臓中濃度

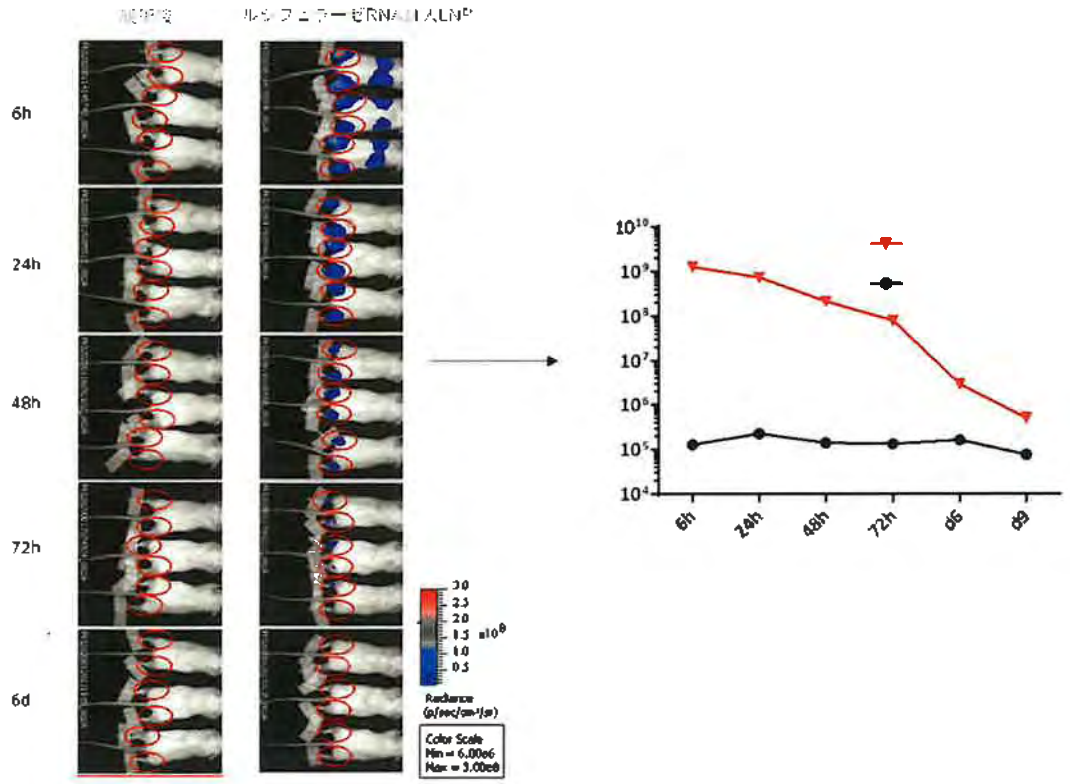


4. 分布

報告書番号：R-[redacted]-0072，185350，概要表：2.6.5.5A，2.6.5.5B

雌性 BALB/c マウス（3 匹）にルシフェラーゼ RNA 封入 LNP を投与し，ルシフェラーゼ発光を代替マーカーとして BNT162b2 の生体内分布を検討した。すなわち，ルシフェラーゼ RNA 封入 LNP をマウスの左右の後肢に各 1 μg RNA（計 2 μg RNA）の用量で筋肉内投与した。その後，ルシフェラーゼ発光検出の 5 分前に発光基質であるルシフェリンを腹腔内投与し，イソフルラン麻酔下，in vivo における発光を Xenogen IVIS Spectrum を用いて投与後 6 および 24 時間ならびに 2，3，6 および 9 日に測定することにより，ルシフェラーゼタンパクの同一個体での経時的な発現推移を評価した。その結果，ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現も投与後 6 時間からみられ，投与後 48 時間までに消失した。肝臓への分布は局所投与したルシフェラーゼ RNA 封入 LNP の一部が循環血中に到達し，肝臓で取り込まれたことを示すものと考えられた。M2.6.4.3 項で詳述したように，ラットにルシフェラーゼ RNA 封入 LNP を静脈内投与した場合には，肝臓が ALC-0315 および ALC-0159 の主要な分布臓器であることが示唆されており，このことはマウスに筋肉内投与した本試験結果の所見と符合するものであった。なお，ラット反復投与毒性試験で肝障害を示す毒性所見は認められていない（M2.6.6.3 項）。

Figure 2 ルシフェラーゼ RNA 封入 LNP を筋肉内投与した BALB/c マウスにおける生体内発光



雌雄 Wistar Han ラットに，[^{3}H]-コレステリルヘキサデシルエーテル（[^{3}H]- CHE）で標識した LNP を用いたルシフェラーゼ RNA 封入 LNP を 50 μg RNA の用量で筋肉内投与し，投与後 15 分ならびに 1，2，4，8，24 および 48 時間の各時点において雌雄各 3 匹から血液，血漿および組織を採取し，液体シンチレーション計数法により放射能濃度を測定することで LNP の生体内分布を評価した。雌雄ともに，放射能濃度はいずれの測定時点においても投与部位が最も高値であった。血漿中の放射能濃度は投与後 1～4 時間で最も高値を示した。また，主に肝臓，脾臓，副腎および卵巣への分布がみられ，これらの組織において放射能濃度が最も高くなったのは投与後 8～48 時間であった。投与部位以外での投与量に対する総放射能回収率は肝臓で最も高く（最大 18%），脾臓（1.0%以下），副腎（0.11%以下）および卵巣（0.095%以下）では肝臓と比較して著しく低かった。また，放射能の平均濃度および組織分布パターンは雌雄でおおむね類似していた。

BNT162b2 がコードする抗原の生体内発現分布は LNP 分布に依存すると考えられる。本試験で用いたルシフェラーゼ RNA 封入 LNP の脂質の構成は，BNT162b2 の申請製剤と同一であることから，本試験結果は BNT162b2 封入 LNP の分布を示すと考えられる。

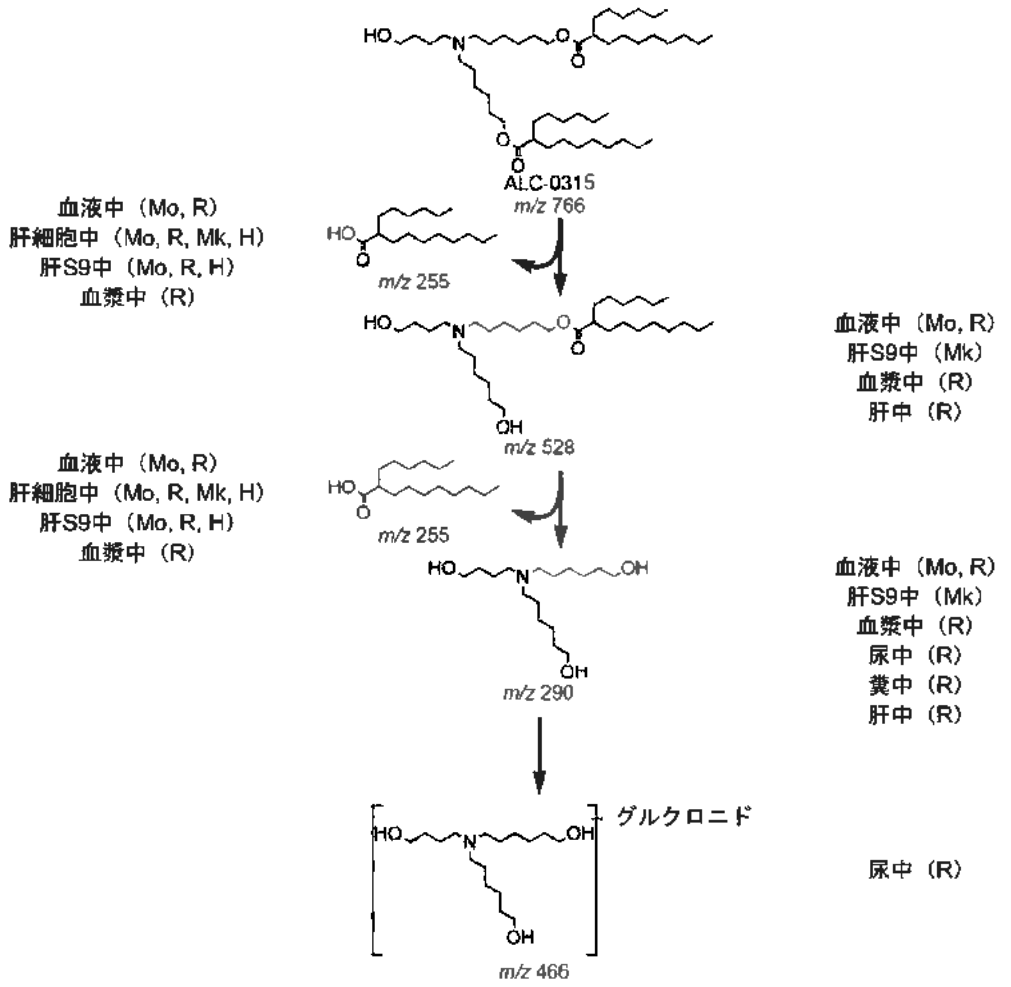
5. 代謝

報告書番号：01049-[redacted]008，01049-[redacted]009，01049-[redacted]010，01049-[redacted]020，01049-[redacted]021，01049-[redacted]022，PF-07302048_05[redacted]_043725，概要表：2.6.5.10A，2.6.5.10B，2.6.5.10C，2.6.5.10D

CD-1/ICR マウス，Wistar Han または Sprague Dawley ラット，カニクイザルならびにヒトの肝ミクロソーム，肝 S9 画分および肝細胞を用いて，ALC-0315 および ALC-0159 の in vitro 代謝安定性を評価した。ALC-0315 または ALC-0159 を各動物種の肝ミクロソームまたは肝 S9 画分（120 分間インキュベーション）もしくは肝細胞（240 分間インキュベーション）に添加して，インキュベーション後の未変化体の割合を測定した。その結果，ALC-0315 および ALC-0159 はいずれの動物種・試験系でも代謝的に安定であり，未変化体の最終的な割合は 82%超であった。

さらに ALC-0315 および ALC-0159 の代謝経路について in vitro および in vivo で評価した。これらの試験では，CD-1 マウス，Wistar Han ラット，カニクイザルおよびヒトの血液，肝 S9 画分および肝細胞を用いて in vitro での代謝を評価した。また，ラット PK 試験で採取した血漿，尿，糞および肝臓試料を用い，in vivo での代謝を評価した（M2.6.4.3 項）。試験結果から，ALC-0315 と ALC-0159 の代謝はいずれも緩徐であり，それぞれエステル結合およびアミド結合の加水分解により代謝されることが明らかになった。Figure 3 および Figure 4 に示した加水分解による代謝は，評価したすべての動物種でみられた。

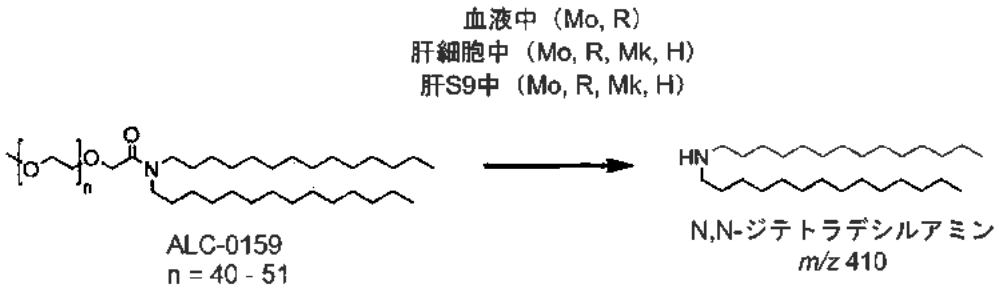
Figure 3 種々の動物種での ALC-0315 の推定生体内代謝経路



H：ヒト，Mk: サル，Mo：マウス，R：ラット

ALC-0315 はエステル加水分解を 2 回連続で受けることにより代謝される。この 2 回の加水分解により，最初，モノエステル代謝物（*m/z* 528），次に二重脱エステル化代謝物（*m/z* 290）が生成される。この二重脱エステル化代謝物はさらに代謝され，グルクロン酸抱合体（*m/z* 466）となるが，このグルクロン酸抱合体はラット PK 試験で尿中にのみ検出された。また，2 回の加水分解の酸性生成物がいずれも 6-ヘキシルデカン酸（*m/z* 255）であることも確認された。

Figure 4 種々の動物種での ALC-0159 の推定生体内代謝経路



H：ヒト，Mk: サル，Mo：マウス，R：ラット

ALC-0159 は，アミド結合の加水分解により *N,N*-ジテトラデシルアミン（*m/z* 410）が生成される経路が主要な代謝経路であった。この代謝物は，マウス・ラットの血液ならびにマウス・ラット・サル・ヒトの肝細胞および肝 S9 画分中に検出された。In vivo 試料からは ALC-0159 の代謝物は確認されなかった。

6. 排泄

ルシフェラーゼ RNA 封入 LNP を 1 mg RNA/kg の用量でラットに静脈内投与した PK 試験（M2.6.4.3 項）で経時的に採取した尿および糞中の ALC-0315 および ALC-0159 濃度を測定した。ALC-0315 および ALC-0159 の未変化体はいずれも尿中に検出されなかった。一方，糞中には ALC-0315 および ALC-0159 の未変化体が検出され，投与量当たりの割合はそれぞれ約 1%および約 50%であった。また，Figure 3 に示したように，ALC-0315 の代謝物が尿中で検出された。

7. 薬物動態学的薬物相互作用

本ワクチンの薬物動態学的薬物相互作用試験は実施していない。

8. その他の薬物動態試験

本ワクチンのその他の薬物動態試験は実施していない。

9. 考察および結論

ラット PK 試験において，血漿および肝臓中 ALC-0315 濃度は，投与後 2 週間までに最高濃度のそれぞれ約 7000 分の 1 および約 4 分の 1 に減少し，ALC-0159 濃度はそれぞれ約 8000 分の 1 および約 250 分の 1 に減少した。t½は血漿中および肝臓中で同程度で，ALC-0315 は 6～8 日，ALC-0159 は 2～3 日であった。血漿中 t½値は，それぞれの脂質が LNP として組織中に分布し，その後，消失過程で血漿中に再分布したことを表すと考えられる。

ALC-0315 の未変化体は尿中と糞中のいずれにもほとんど検出されなかったが，ラット PK 試験で採取した糞および血漿試料からモノエステル代謝物，二重脱エステル化代謝物および 6-ヘキシルデカン酸が，尿からは二重脱エステル化代謝物のグルクロン酸抱合体が検出された。この代謝過程が ALC-0315 の主要消失機序と考えられるが，この仮説を検証する定量データは得られていない。一方，ALC-0159 は投与量の約 50%が未変化体として糞中に排泄された。In vitro 代謝実験において，アミド結合の加水分解により緩徐に代謝された。

BNT162b2 がコードする抗原の生体内発現分布は LNP 分布に依存すると考えられることから，BALB/c マウスにルシフェラーゼ RNA 封入 LNP を筋肉内投与し，代替レポータータンパク質の生体内分布を検討した。その結果，ルシフェラーゼの発現が投与部位においてみられ，それより発現量は低値であったものの肝臓でも認められた。ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現は投与後 6 時間から認められ，投与後 48 時間までに消失した。肝臓への分布は局所投与したルシフェラーゼ RNA 封入 LNP が循環血中に到達し，肝臓で取り込まれたことを示すものと考えられた。また，ラットにルシフェラーゼ RNA 封入 LNP の放射能標識体を筋肉内投与したところ，放射能濃度は投与部位で最も高値を示した。投与部位以外では，肝臓で最も高く，次いで脾臓，副腎および卵巣でも検出されたが，これらの組織における投与量に対する総放射能回収率は肝臓より著しく低かった。この結果は，マウス生体内分布試験において肝臓でルシフェラーゼ発現がみられたことと符合した。なお，ラット反復投与毒性試験で肝障害を示す毒性所見は認められなかった（M2.6.6.3 項）。

以上の非臨床薬物動態評価より，循環血中に到達した LNP は肝臓に分布することが示された。また，ALC-0315 および ALC-0159 の消失には，それぞれ代謝および糞中排泄が関与することが示唆された。

2.6.5.3. PHARMACOKINETICS: PHARMACOKINETICS AFTER A SINGLE DOSE

Test Article: modRNA encoding luciferase in LNP
Report Number: PF-07302048_06[redacted]_072424

Species (Strain)	Rat (Wistar Han)	
Sex/Number of Animals	Male/ 3 animals per timepoint[a]	
Feeding Condition	Fasted	
Method of Administration	IV	
Dose modRNA (mg/kg)	1	
Dose ALC-0159 (mg/kg)	1.96	
Dose ALC-0315 (mg/kg)	15.3	
Sample Matrix	Plasma, liver, urine and feces	
Sampling Time Points (h post dose):	Predose, 0.1, 0.25, 0.5, 1, 3, 6, 24, 48, 96, 192, 336	
Analyte	ALC-0315	ALC-0159
PK Parameters:	Mean[b]	Mean[b]
AUC_{inf} (µg•h/mL)[c]	1030	99.2
AUC_{last} (µg•h/mL)	1020	98.6
Initial $t_{½}$ (h)[d]	1.62	1.74
Terminal elimination $t_{½}$ (h)[e]	139	72.7
Estimated fraction of dose distributed to liver (%)[f]	59.5	20.3
Dose in Urine (%)	NC[g]	NC[g]
Dose in Feces (%)[h]	1.05	47.2

ALC-0159 = 2-[(polyethylene glycol)-2000]-N,N-ditetradecylacetamide), a proprietary polyethylene glycol-lipid included as an excipient in the LNP formulation used in BNT162b2; ALC-0315 = (4-hydroxybutyl)azanediyl)bis(hexane-6,1-diyl)bis(2-hexyldecanoate), a proprietary aminolipid included as an excipient in the LNP formulation used in BNT162b2; AUC_{inf} = Area under the plasma drug concentration-time curve from 0 to infinite time; AUC_{last} = Area under the plasma drug concentration-time curve from 0 to the last quantifiable time point; BLQ = Below the limit of quantitation; LNP = Lipid nanoparticle; modRNA = Nucleoside modified messenger RNA; PK = Pharmacokinetics; $t_{½}$ = Half-life.

a. Non-serial sampling, 36 animals total.
b. Only mean PK parameters are reported due to non-serial sampling.
c. Calculated using the terminal log-linear phase (determined using 48, 96, 192, and 336 h for regression calculation).
d. ln(2)/initial elimination rate constant (determined using 1, 3, and 6 h for regression calculation).
e. ln(2)/terminal elimination rate constant (determined using 48, 96, 192, and 336 h for regression calculation).
f. Calculated as follows: highest mean amount in the liver (µg)/total mean dose (µg) of ALC-0315 or ALC-0159.
g. Not calculated due to BLQ data.
h. Fecal excretion, calculated as: (mean µg of analyte in feces/ mean µg of analyte administered) × 100

2.6.5.5A. PHARMACOKINETICS: ORGAN DISTRIBUTION

Test Article: modRNA encoding luciferase in LNP
Report Number: R-[redacted]-0072

Species (Strain):	Mice (BALB/c)
Sex/Number of Animals:	Female/3 per group
Feeding Condition:	Fed ad libitum
Vehicle/Formulation:	Phosphate-buffered saline
Method of Administration:	Intramuscular injection
Dose (mg/kg):	1 µg/hind leg in gastrocnemius muscle (2 µg total)
Number of Doses:	1
Detection:	Bioluminescence measurement
Sampling Time (hour):	6, 24, 48, 72 hours; 6 and 9 days post-injection

Time point	Total Mean Bioluminescence signal (photons/second)		Mean Bioluminescence signal in the liver (photons/second)
	Buffer control	modRNALuciferase in LNP	modRNALuciferase in LNP
6 hours	1.28×10^{5}	1.26×10^{9}	4.94×10^{7}
24 hours	2.28×10^{5}	7.31×10^{8}	2.4×10^{6}
48 hours	1.40×10^{5}	2.10×10^{8}	Below detection[a]
72 hours	1.33×10^{5}	7.87×10^{7}	Below detection[a]
6 days	1.62×10^{5}	2.92×10^{6}	Below detection[a]
9 days	7.66×10^{4}	5.09×10^{5}	Below detection[a]

LNP = Lipid nanoparticle; modRNA = Nucleoside modified messenger RNA.
a. At or below the background level of the buffer control.

Test Article: [^{3}H]-Labelled LNP-mRNA formulation containing ALC-0315 and ALC-0159
Report Number: 185350

-- = Not applicable, partial tissue taken; [^{3}H]-08-A01-C0 = An aqueous dispersion of LNPs, including ALC-0315, ALC-0159, distearoylphosphatidylcholine, cholesterol, mRNA encoding luciferase and trace amounts of radiolabeled [Cholesteryl-1,2-3H(N)]-Cholesteryl Hexadecyl Ether, a nonexchangeable, non-metabolizable lipid marker used to monitor the disposition of the LNPs; ALC-0159 = 2-[(polyethylene glycol)-2000]-N,N--ditetradecylacetamide), a proprietary polyethylene glycol-lipid included as an excipient in the LNP formulation used in BNT162b2; ALC-0315 = (4--hydroxybutyl)azanediyl)bis(hexane-6,1-diyl)bis(2-hexyldecanoate), a proprietary aminolipid included as an excipient in the LNP formulation used in BNT162b2; LNP = Lipid nanoparticle; mRNA = messenger RNA.

a. The mean male and female blood:plasma values were first calculated separately and this value represents the mean of the two values.

2.6.5.9. PHARMACOKINETICS: METABOLISM IN VIVO, RAT

Test Article: modRNA encoding luciferase in LNP
Report Number: PF-07302048_05[redacted]_043725

Species (Strain):	Rat (Wistar Han)
Sex/ Number of animals	Male/ 36 animals total for plasma and liver, 3 animals for urine and feces
Method of Administration:	Intravenous
Dose (mg/kg):	1
Test System:	Plasma, Urine, Feces, Liver
Analysis Method:	Ultrahigh performance liquid chromatography/ mass spectrometry

Biotransformation	m/z	Metabolites of ALC-0315 Detected

1. Background information on the procedure

1.1. Submission of the dossier

The applicant BioNTech Manufacturing GmbH submitted on 30 November 2020 an application for marketing authorisation to the European Medicines Agency (EMA) for Comirnaty, through the centralised procedure falling within the Article 3(1) and point 1 of Annex of Regulation (EC) No 726/2004. The eligibility to the centralised procedure was agreed upon by the EMA/CHMP on 23 July 2020.

The applicant applied for the following indication:

"Active immunisation to prevent COVID-19 disease caused by SARS-CoV-2 virus, in individuals 16 years of age and older. The use of Comirnaty vaccine should be in accordance with official guidance."

The legal basis for this application refers to:

Article 8.3 of Directive 2001/83/EC - complete and independent application.

The application submitted is composed of administrative information, complete quality data, non-clinical and clinical data based on applicants' own tests and studies and/or bibliographic literature substituting/supporting certain tests or studies.

Information on Paediatric requirements

Pursuant to Article 7 of Regulation (EC) No 1901/2006, the application included an EMA Decision P/0480/2020 on the agreement of a paediatric investigation plan (PIP).

At the time of submission of the application, the PIP P/0480/2020 was not yet completed as some measures were deferred.

Similarity

Pursuant to Article 8 of Regulation (EC) No. 141/2000 and Article 3 of Commission Regulation (EC) No 847/2000, the applicant did not submit a critical report addressing the possible similarity with authorised orphan medicinal products because there is no authorised orphan medicinal product for a condition related to the proposed indication.

Conditional marketing authorisation

The applicant requested consideration of its application for a Conditional marketing authorisation in accordance with Article 14-a of the above-mentioned Regulation, as it is intended for the prophylaxis of a life-threatening disease. In addition, the above-mentioned medicinal product is intended for use in an emergency situation, in response to public health threats duly recognised by the World Health Organisation and by the Union.

New active Substance status

The applicant requested the active substance Single-stranded, 5'-capped messenger RNA produced using a cell-free in vitro transcription from the corresponding DNA templates, encoding the viral spike

(S) protein of SARS-CoV-2 contained in the above medicinal product to be considered as a new active substance, as the applicant claims that it is not a constituent of a medicinal product previously authorised within the European Union.

Scientific advice

The applicant did not seek Scientific advice from the CHMP.

COVID-19 EMA pandemic Task Force (COVID-ETF)

In line with their mandate as per the EMA Emerging Health Threats Plan, the ETF undertook the following activities in the context of this marketing authorisation application:

The ETF confirmed eligibility to the rolling review procedure based on the information provided by the applicant and agreed the start of the rolling review procedure.

Furthermore, the ETF discussed the (Co-)Rapporteur's assessment reports overviews and provided their recommendation to the CHMP in preparation of the written adoption rolling review procedures. The corresponding interim opinions were subsequently adopted by the CHMP.

For the exact steps taken at ETF, please refer to section 1.2.

1.2. Steps taken for the assessment of the product[2]

The Rapporteur and Co-Rapporteur appointed by the CHMP were:

Rapporteur: Filip Josephson Co-Rapporteur: Jean-Michel Race

The CHMP confirmed eligibility to the centralised procedure on	23 July 2020
Confirmation by ETF on the eligibly to the rolling review procedure on	24 July 2020
Agreement by ETF to start the rolling review procedure on	25 September 2020
The applicant submitted documentation as part of a rolling review on non-clinical data to support the marketing authorisation application	05 October 2020
The procedure (Rolling Review 1) started on	06 October 2020
The Rapporteur's first Assessment Report was circulated to all CHMP, Peer Reviewer and ETF on	22 October 2020
The Rapporteurs circulated updated Joint Assessment reports to all CHMP, Peer Reviewer and ETF on	28 October 2020
ETF discussions took place on	29 October 2020
Adoption of first Interim Opinion on the RR via 24 hour written procedure on	06 November 2020
The applicant submitted documentation as part of a rolling review on quality data to support the marketing authorisation application	06 November 2020

[2] These steps do not reflect the additional submissions made by the applicant during the active assessment phases.

The procedure (Rolling Review 2) started on	07 November 2020
The Rapporteur's first Assessment Report was circulated to all CHMP, BWP, Peer Reviewer and ETF on	19 November 2020
BWP extraordinary adobe meeting was held on	24 November 2020
Updated joint draft overview and LoQ drafted by Rapporteurs and circulated to CHMP and ETF on	25 November 2020
ETF discussions took place on	26 November 2020
Adoption of the 2nd interim opinion for this rolling review on	30 November 2020
The application for the marketing authorisation was formally received by the EMA on	30 November 2020
The procedure started on	1 December 2020
BWP extraordinary adobe meeting was held on	15 December 2020
The Rapporteur's first Assessment Report was circulated to all CHMP, BWP, peer reviewer and ETF on	16 December 2020
The Co-Rapporteur's first Assessment Report was circulated to all CHMP members on	16 December 2020
BWP extraordinary adobe meeting with an Oral Explanation by the applicant was held on	16 December 2020
ETF discussions took place on	17 December 2020
The Rapporteurs circulated the Joint Assessment Report to all CHMP members on	17 December 2020
BWP extraordinary adobe meeting was held on	18 December 2020
The PRAC agreed on the PRAC Assessment Overview and Advice to CHMP during an extraordinary meeting on	18 December 2020
CHMP extraordinary adobe meeting was held on	18 December 2020
The following GMP and GLP inspections were requested by the CHMP and their outcome taken into consideration as part of the Quality/Safety/Efficacy assessment of the product:	
– GMP inspections (distant assessments) of the sites Wyeth BioPharma, Andover (manufacturer DS, QC DS, QC DP) and Pfizer Inc., Chesterfield (QC DP, QC DP), both located in the USA, were carried out between 20 November 2020 and 02 December 2020. The outcome of the inspections carried out were issued on 15 December 2020.	15 December 2020
– A GLP inspection at a CRO in Germany between 3 to 6 November 2020. The outcome of the inspection carried out was issued on 6 November 2020.	6 November 2020

The CHMP, in the light of the overall data submitted and the scientific discussion within the Committee, issued a positive opinion for granting a conditional marketing authorisation to Comirnaty on	21 December 2020

2. Scientific discussion

2.1. Problem statement

2.1.1. Disease or condition

COVID-19 is caused by SARS-CoV-2, a zoonotic virus that first emerged as a human pathogen in China and has rapidly spread around the world by human to human transmission. In December 2019, a pneumonia outbreak of unknown cause occurred in Wuhan, China. In January 2020, it became clear that a novel Coronavirus (2019-nCoV) was the underlying cause. In early January 2020, the genetic sequence of the 2019-nCoV became available to the World Health Organization (WHO) and public, and the virus was categorized in the Betacoronavirus subfamily. By sequence analysis, the phylogenetic tree revealed a closer relationship to severe acute respiratory syndrome (SARS) virus isolates than to other coronaviruses that infect humans, including the Middle East respiratory syndrome (MERS) coronavirus. SARS-CoV-2 infections and the resulting disease COVID-19 have spread globally, affecting a growing number of countries. On 11 March 2020 the WHO characterized the COVID-19 outbreak as a pandemic. As of 01 December 2020, there have been >63 million globally confirmed COVID-19 cases and >1.4 million deaths, with 191 countries/regions affected.

At the time of this marketing application submission, confirmed cases and mortality continue to rise globally. The ongoing pandemic remains a significant challenge to public health and economic stability worldwide.

2.1.2. Epidemiology and risk factors

Every individual is at risk of infection as there is no pre-existing immunity to the SARS-CoV-2. Following infection some but not all individuals develop protective immunity in terms of neutralising antibody responses and cell mediated immunity. However, it is currently unknown to what extent and for how long this protection lasts.

According to WHO 80% of infected individuals recover without need for hospital care, while 15% develop more severe disease and 5% need intensive care.

Increasing age and underlying medical conditions are considered risk factors for developing severe disease.

2.1.3. Aetiology and pathogenesis

SARS-CoV-2 is an RNA virus with four structural proteins. One of them, the Spike protein is a surface protein which binds the angiotensin-converting enzyme 2 (ACE-2) present on host cells. Therefore, the Spike protein is considered a relevant antigen for vaccine development. It has been shown that antibodies against the Spike protein neutralise the virus and prevent infection.

2.1.4. Clinical presentation and diagnosis

The presentation of COVID-19 is generally with cough and fever, with chest radiography showing ground-glass opacities or patchy shadowing. However, many patients present without fever or radiographic changes, and infections may be asymptomatic which is relevant to controlling transmission. For symptomatic subjects, progression of disease may lead to acute respiratory distress syndrome requiring ventilation and subsequent multi-organ failure and death.

Common symptoms in hospitalized patients (in order of highest to lowest frequency) include fever, dry cough, shortness of breath, fatigue, myalgias, nausea/vomiting or diarrhoea, headache, weakness, and rhinorrhoea. Anosmia (loss of smell) or ageusia (loss of taste) may be the sole presenting symptom in approximately 3% of individuals who have COVID-19.

The US Centres for Disease Control and Prevention (CDC) defined COVID-19 symptoms as including 1 or more of the following:

- Fever
- New or increased cough
- New or increased shortness of breath
- Chills
- New or increased muscle pain
- New loss of taste or smell
- Sore throat
- Diarrheal
- Vomiting
- Fatigue
- Headache
- Nasal congestion or runny nose
- Nausea

All ages may present with the disease, but notably case fatality rates (CFR) are elevated in persons >60 years of age. For example, in Italy the CFR was 0.3% in adults <40 years of age but 12.8% in adults 70 to 79 years of age and 20.2% in patients ≥80 years of age. Comorbidities are also associated with increased CFR, including cardiovascular disease, diabetes, hypertension, and chronic respiratory disease. Healthcare workers are overrepresented among COVID-19 patients due to occupational exposure to infected patients.

In most situations, a molecular test is used to detect SARS-CoV-2 and confirm infection. The reverse transcription polymerase chain reaction (RT-PCR) test methods targeting SARS-CoV-2 viral RNA are the gold standard in vitro methods for diagnosing suspected cases of COVID-19. Samples to be tested are collected from the nose and/or throat with a swab. Molecular methods used to confirm an active infection are usually performed within a few days of exposure and around the time that symptoms may begin.

2.1.5. Management

The management of COVID-19 has developed during 2020, and now includes antiviral therapy (e.g. remdesivir), antibodies administered from convalescent plasma and hyperimmune immunoglobulins, anti-inflammatory agents such as dexamethasone and statins, targeted immunomodulatory agents and anticoagulants. These therapies have shown variable and limited impact on the severity and duration of illness, with different efficacies depending on the stage of illness and manifestations of disease.

While care for individuals who have COVID-19 has improved with clinical experience, there remains an urgent and unmet medical need for a prophylactic vaccine during the ongoing pandemic, both for protection of particularly vulnerable groups as well as mitigating the effects of the pandemic at a population level, e.g. to maintain a functioning health care system, and to avoid the social and economic consequences of the stringent measures needed to diminish virus spread. There is currently no approved vaccine in EU for prevention of COVID-19.

About the product

BNT162b is a mRNA vaccine for prevention of COVID-19. The vaccine is made of a mRNA encoding for the full-length SARS-CoV-2 spike glycoprotein (S) encapsulated in lipid nanoparticles (LNPs). The sequence of the S protein was chosen based on the sequence for the "SARS-CoV-2 isolate Wuhan-Hu-1", which was available when the program was initiated: GenBank: MN908947.3 (complete genome) and GenBank: QHD43416.1 (spike surface glycoprotein).

The active substance consists of a single-stranded, 5'-capped mRNA that is translated into a codon-optimized sequence encoding the spike antigen of SARS-CoV-2. The RNA contains common structural elements optimized for mediating high RNA stability and translational efficiency (see section 2.2). The LNPs protect the RNA from degradation by RNAses and enable transfection of host cells after intramuscular (IM) delivery.

The mRNA is translated into the SARS-CoV-2 S protein in the host cell cytosol. The S protein is then expressed on the cell surface where it induces an adaptive immune response. The S protein is identified as a target for neutralising antibodies against the virus and is therefore considered a relevant vaccine component.

The vaccine, BNT162b2 (30 µg), is administered intramuscularly (IM) in two 30 µg doses of the diluted vaccine solution given 21 days apart.

Intended indication: *'Active immunisation to prevent COVID-19 disease caused by SARS-CoV-2 virus, in individuals 16 years of age and older'.*

Type of Application and aspects on development

The applicant requested consideration of its application for a Conditional Marketing Authorisation in accordance with Article 14-a of the above-mentioned Regulation, based on the following criteria:

- The benefit-risk balance is positive:

According to the Applicant, there is a positive benefit-risk balance for Comirnaty in the active immunisation to prevent COVID-19 disease caused by SARS-CoV-2, in individuals 16 years of age and older. This is based on evidence from the pivotal study C4591001 (also referred to as BNT162-02), a Phase 1/2/3, placebo-controlled, randomized, observer-blind, dose-finding Study investigating the safety, tolerability, immunogenicity, and efficacy of SARS-COV-2 RNA Vaccine Candidates Against COVID-19 in healthy individuals.

The Applicant stated that the available data to date indicate that its vaccine was 95 percent effective and had no serious side effects, showing that the vaccine prevented mild and severe forms of COVID-19.

- It is likely that the applicant will be able to provide comprehensive data.

The Applicant intends to continue the ongoing pivotal Phase 3 study with participants as originally allocated for as long as possible, to obtain long-term data and to ensure sufficient follow-up to support a standard marketing authorisation. In case of availability of any COVID-19 vaccine, the sponsor will appeal to participants to remain in the ongoing study as originally randomized for as long as possible, ideally until a COVID-19 vaccine has full regulatory approval. In all cases, it is intended to follow participants up to the original planned 24 months post-vaccination, regardless of any participants opting to crossover from placebo to active vaccination. The safety and effectiveness of COMIRNATY in individuals <16 years of age have not been established for this application. Four studies in paediatric subjects are planned as laid down in the paediatric investigation plan. A study in pregnant women is also planned in the EU. A Post-Approval Active Surveillance Safety Study to Monitor Real-World Safety of Comirnaty (Study C4591010) will be conducted in the EU using primary data collection that monitors a cohort of vaccinees and evaluates risk of AESIs. The Applicant will also conduct, non-interventional studies (test negative design) of individuals presenting to the hospital or emergency room with symptoms of potential COVID-19 in a real-world setting. These studies will allow to determine the effectiveness of vaccine in a real-world setting and against severe disease, and in specific racial, ethnic, and age groups.

- Unmet medical needs will be addressed

According to the Applicant, as there is no approved other vaccine in the EU or successful COVID-19 therapy available in the EU, unmet medical need is existing and is likely to be addressed by this vaccine in view of the high level of protection observed in the pivotal clinical trial.

- The benefits to public health of the immediate availability outweigh the risks inherent in the fact that additional data are still required.

According to the Applicant, Efficacy of COMIRNATY to prevent COVID-19 was demonstrated at the final analysis. The observed VE in each subgroup as defined by age, including elderly ≥ 65 years old, sex, race/ethnicity, country, obese subjects, and subjects at risk due to comorbidities, was overall consistent with the effectiveness of BNT162b2 to protect vaccinees against the disease. The benefit of immediate availability of Comirnaty through conditional marketing authorisation is based on the fact that there is no approved vaccine or successful COVID-19 therapy available in the European Union. An effective vaccine can impact the pandemic at this critical time and a COVID-19 vaccination program implemented soon can likely prevent further pandemic waves and thus substantially reduce mortality due to disease.

2.2. Quality aspects

2.2.1. Introduction

The finished product is presented as a concentrate for dispersion for injection containing 225 µg/ 0.45 mL (prior to dilution) of BNT162b2 (5'capped mRNA encoding full length SARS-CoV-2 Spike protein) as active substance (AS).

Other ingredients are: ALC-0315 (4-hydroxybutyl)azanediyl)bis(hexane-6,1-diyl)bis(2-hexyldecanoate), ALC-0159 (2-[(polyethylene glycol)-2000]-N,N-ditetradecylacetamide), 1,2-

Distearoyl-sn-glycero-3-phosphocholine (DSPC), cholesterol, potassium chloride, potassium dihydrogen phosphate, sodium chloride, disodium phosphate dihydrate, sucrose and water for injections.

The product is available in a 2 mL clear vial (type I glass) with a stopper (synthetic bromobutyl rubber) and a flip-off plastic cap with aluminium seal. Pack size: 195 vials.

The multidose (5 dose) vial is stored frozen and must be thawed prior to dilution. After thawing, the vaccine should be diluted and used immediately.

After dilution with 1.8 mL sodium chloride (0.9%) solution (not supplied), one dose (0.3 mL) contains 30 micrograms of COVID-19 mRNA Vaccine (embedded in lipid nanoparticles).

2.2.2. Active Substance

General Information

The active substance consists of a single-stranded, 5'-capped mRNA that is translated into a codon-optimised sequence encoding the spike antigen of SARS-CoV-2. The vaccine is based on the spike glycoprotein (S) of SARS-CoV-2. The sequence was chosen based on the sequence for the "Severe acute respiratory syndrome coronavirus 2 isolate Wuhan-Hu-1". The protein sequence contains two proline mutation, which ensures an antigenically optimal pre-fusion confirmation (P2 S). The RNA does not contain any uridines; instead of uridine the modified N1-methylpseudouridine is used in RNA synthesis. The applicant will provide clarification on the mechanism of action for BNT162b2.

Manufacture, process controls and characterisation

Manufacturers

The active substance is manufactured and controlled by either Wyeth BioPharma Division, Andover, United States or by BioNTech Manufacturing GmbH, Mainz, Germany, and Rentschler Biopharma SE, Laupheim, Germany.

During the procedure, a number of issues were highlighted relating to the GMP status of the manufacture of the active substance and of the testing sites of the finished product for the purpose of batch release. These issues were classified as a Major Objection (MO). After further information was obtained from the sites and inspectors, the MO was considered resolved.

EU GMP certificates for the manufacturing and testing sites were subsequently obtained. In conclusion, appropriate manufacturing authorisations and GMP certificates are in place for all active substance and finished product manufacturing sites.

Description of manufacturing process and process controls

Information on the manufacturing process and process controls for both the Andover and the BNT Mainz & Rentschler manufacturing sites were provided.

The manufacturing process of BNT162b2 active substance involves five major steps. The RNA is synthesised from linear DNA via an in vitro transcription (IVT) step. The IVT step is followed by a number of purification and filtration steps. Lastly, the RNA undergoes a final filtration before being dispensed and stored frozen.

Flow diagrams were provided, presenting the process steps, process inputs and the process controls for each step. The purpose of each step in the manufacturing process is sufficiently described. The ranges of hold times and process parameters and routine in-process controls are listed with corresponding acceptance criteria, for each step. It is noted that not all process parameters are listed, but that the lists include all critical and several non-critical process parameters. It is agreed that the key process parameters are described in the dossier. The applicant has agreed to upgrade these parameters to critical process parameters (CPPs) and to include acceptable ranges for these CPPs. Updated information has been submitted during the procedure which comprised modifications of the acceptable ranges of several process parameters and the addition of some controls. The strategy is found acceptable, and the Applicant will provide information on acceptable ranges for some parameters.

The active substance is stored between -15°C and -25°C. Transportation using an insulated shipper is qualified and shipping time to finished product manufacturing sites are defined. Shipping validation of the intermediate has been agreed as recommendation.

The batch numbering system is sufficiently described.

Control of materials

An adequate overview of the raw materials and solutions used in the active substance manufacturing process is provided.

Representative certificates of analysis have been provided. The submitted information supports the appropriate quality of raw materials. It is recommended that the applicant should implement relevant testing strategies to ensure an adequate microbiological control for the starting materials **(REC1)** and should implement a relevant testing strategy to ensure that HEPES (Pfizer) raw material, included in the formulation buffer of FP, is free from contaminating RNases **(REC2).** The description of synthesis of 5'cap and its related impurities were requested during the procedure. Appropriate information was given. The applicant should implement in-house functional activity analytical methods for release testing of enzymes used in the manufacturing process at all relevant manufacturing sites, by Q1 2021 **(REC3)**.

The BNT162b2 active substance is manufactured by in vitro transcription using a linear DNA template, produced via plasmid DNA from transformed *Escherichia coli* cells.

The linear DNA template is not part of the final product but defines the sequence of the mRNA product and therefore it is fundamental to ensure the adequate control of the active substance. Changes to the manufacturing process of the linear DNA template (e.g. change to plasmid host cell) may result in a different impurity profile in the active substance. Additional details on the manufacturing process and the control strategy for this starting material, initially only shortly described, have been provided and the dossier will be updated accordingly.

The cell banks involved in the plasmid manufacturing process are described. Master cell bank (MCB) and working cell bank (WCB) qualification tests are listed. Relevant specifications are set and data from the current MCB and WCB are provided. The plasmid MCBs and WCBs are enrolled in a cell bank stability program. The strategy is considered adequate, noting that the dossier will be updated as appropriate. A protocol for establishment of future WCBs is provided.

Following fermentation, the cells are harvested and chemically lysed to recover the plasmid DNA. After this lysis step, the circular plasmid DNA is purified. The circular plasmid DNA is filtered and stored frozen. The strategy for establishing the initial shelf-life is endorsed and data provided support the proposed shelf life. A list of the raw materials as well as other materials used in the manufacture of the

linear DNA template is provided. All materials used are animal origin free and sourced from approved suppliers.

Specifications for the circular plasmid DNA as well as for the DNA linear template are provided. Process- and product-related impurities including host cell genomic DNA, RNA, proteins, endotoxins, bioburden and plasmid isoforms, for the plasmid DNA, are routinely quantified. The reference material is described. Implementation of any changes in the manufacture of the linear DNA template should be applied for in a variation application.

Control of critical steps and intermediates

Process parameters and tests that are used to control the process and active substance quality are provided. The list of CPPs was provided with corresponding updated acceptable ranges.

A summary of the quality attributes with the rationale for the criticality assignment is provided. The rationale for classification into CQA or QA is presented for each attribute and appears reasonable.

The in-process test methods are defined and described in the dossier.

Acceptable information has been provided on the control system in place to monitor and control the active substance manufacturing process with regard to critical, as well as non-critical operational parameters and in-process tests. Actions taken if limits are exceeded are specified.

Process validation

The BNT162b2 active substance manufacturing process has been validated adequately. Consistency in production has been shown on full scale commercial process validation/ process performance qualification batches at all sites. All acceptance criteria for the critical operational parameters and acceptance criteria for the in-process tests are fulfilled demonstrating that the purification process consistently produces active substance of reproducible quality that complies with the predetermined specification and in-process acceptance criteria.

In comparability studies, a decrease in RNA integrity was observed for the initial Process 2 batches compared to Process 1 batches. This is further discussed in the subsequent section on manufacturing process development. After adjustment of process parameters for CTP and ATP volumes, RNA integrity level is more consistent and verify that the volume adjustments made for ATP and CTP volumes consistently provide reproducible results with RNA integrity levels more similar to levels achieved in Process 1 batches. Since the target volumes for ATP and CTP have been increased, the proven acceptable ranges (PARs) ranges need to be adjusted and the dossier updated accordingly **(REC8)**. The robustness of the DNase digestion step is not considered comprehensively demonstrated although there is routine control of residual DNA impurities at the active substance level. It has been confirmed that studies to enhance the robustness of this step are ongoing and these should be reported **(REC7).** The finalised indirect filter qualification assessment, according to the applicant, already available and should be provided for evaluation **(REC6).**

Relevant hold times and transport times have been defined and were validated by appropriate studies.

The shipping qualification strategy is described in detail and considers both thermal and mechanical aspects of shipping. The shipping procedures and configuration for transport of frozen AS to the

finished product manufacturing sites were validated to maintain product temperature in the acceptable range for a defined duration.

A transport verification study is planned and results will be available in Q1/2021. The recommendation to provide shipping performance qualification data has been agreed **(REC6)**.

Manufacturing process development

Process development changes were adequately summarised. Two active substance processes have been used during the development history; Process 1 (clinical trial material) and Process 2 (commercial process). Details about process differences, justification for making changes, and results from a comparability study are provided. The major changes between active substance process versions were described in the dossier.

Batch analysis results showing comparability between non-clinical and clinical batches are provided. Additional characterization of product-related species and their relation to final product specifications will be provided as a specific obligation.

Electropherograms were presented demonstrating similarities in the peak pattern of RNA species, but some differences between Process 1 and 2 were also noted. It can therefore not be concluded that identical species are obtained by the processes. It is likely that the fragmented species will not result in expressed proteins, due to their expected poor stability and poor translational efficiency (see below). However, the lack of experimental data on the truncated RNA and expressed proteins does not permit a definitive conclusion and needs further characterisation. Therefore, additional characterisation data remain to be provided as a specific obligation **(SO1)**.

Regarding the 5′ cap end of the AS, reversed phase high performance liquid chromatography-UV and mass spectrometry (LC- UV/MS) characterisation confirmed that the 5'-capped and uncapped structures are the same but that there is a slight shift towards higher 5'-capping levels in Process 2. The reported quality attribute 'capped-intact RNA' is intended to reflect the proportion of the RNA molecules in the active substance that are a fully intact molecule and have the 5′-cap. It is noted that the capped-intact RNA is not measured, but only calculated from the results of 5′-cap and %RNA integrity tests. Therefore, this argument alone cannot fully confirm the comparability of Process 2 versus Process 1, and further characterisation data and justification of specifications were requested.

According to the Applicant, the majority of fragments are expected to be comprised of truncated transcripts including the 5′ region but lacking the 3′ region and poly(A)tail. However, the results indicating a substantial proportion of shorter/truncated mRNA with both cap and poly(A)tail are not in agreement with this statement. Therefore, the Applicant was asked to discuss and justify the obtained results and explain the apparent discrepancy. Additional characterisation data using an orthogonal method with enriched samples for fragmented species was provided. Preliminary characterization data on isolated fragmented species suggests they predominantly include the 5′-cap but lack the poly(A) tail, supporting the hypothesis that most fragments would arise from premature termination in the IVT reaction. The characterisation data are requested to be completed with analysis of the main peak from ion pairing RP-HPLC and analysis of other samples from Process 1 and optimised Process 2 **(SO1).** The Applicant will continue to evaluate any potential overestimation of poly(A) tail and should characterise fragments for any future AS process changes **(SO1)**.

Furthermore, the poly(A)tail of the 3′ end was characterised by LC-UV/MS. While the results were demonstrated to be comparable between Process 1 and Process 2 batches, significant differences were identified. As expected, poly(A) tail heterogeneity was observed both for Process 1 and Process 2 batches. Thus, slight differences in the poly(A)tail pattern were observed when comparing Process 1

and Process 2 AS batches. The Applicant explains that the redistribution is probably due to the use of a linearised DNA plasmid template in Process 2 instead of a PCR-derived DNA template in Process 1. For both processes, the poly(A)tail is anticipated to be sufficiently long to guarantee stability of the RNA and function in translation. This explanation is considered reasonable by the CHMP.

The overall primary sequence of BNT162b2 active substance was demonstrated to be comparable by LC/MS/MS -oligonucleotide mapping. Circular dichroism (CD) spectroscopy confirmed that the higher-order structure of Process 1 and Process 2 AS batches were comparable.

To demonstrate functionality, the protein size after in-vitro expression of BNT162b2 active substance was determined. The expressed protein sizes were demonstrated to be comparable between Process 1 and Process 2 batches. However, further clarification is requested and include correlation with the calculated molecular weights of the intact S1S2 protein should be demonstrated. **(SO1).**

A second comparability study was presented to assess comparability across the Process 2 manufacturing facilities, batches each from the Andover and BioNTech sites were included in the study. In addition, Process 2 batches, planned for clinical supply and for emergency supply in the US market and representative batches from Process 1 were included in the comparison.

In conclusion, the Process 2 batches manufactured at the Andover and BioNTech sites were demonstrated to be comparable with respect to identity as monitored by agarose gels and 5'Cap structure characterised by LC-UV and subsequent MS analysis. Furthermore, the primary sequence and the secondary structure was demonstrated to be comparable for all Process 1 and Process 2 batches included in the study. Poly(A) tail length and distribution was investigated by RP-HPLC and MS analysis. All process 2 batches were found comparable, while the Process 1 batches showed a somewhat different poly(A) tail pattern.

The expressed protein size after in-vitro expression of BNT162b2 active substance was determined and the results demonstrate comparability between batches. However, the identity of the bands identified by WB are not sufficiently justified and further clarification is requested **(SO1)**.

Overall, the submitted data confirm consistent and comparable quality of Process 2 batches manufactured at the Andover and BioNTech sites.

Process characterisation studies using scale-down models of individual unit operations, were performed.

It should be noted that future changes to any of the process parameters, regardless of the classification of CPP or non-CPP, should be applied for as variation to the terms of the MA.

Initially, addition volumes for ATP and CTP were identified as non-CPPs as both were supplied in theoretical excess. Following additional manufacturing campaigns and additional small-scale studies it was shown that these volumes could be limiting, and the ranges were widened at the higher end. It is noted that after the adjustment of these volumes, the percentage of RNA integrity has increased to levels more consistent with Process 1 batches. Nevertheless, since the target volumes for ATP and CTP have been increased to avoid that these nucleotides are rate-limiting in order to increase the percentage of RNA integrity, the PAR ranges need to be adjusted and the dossier updated accordingly **(REC8)**.

The acceptable ranges for CPPs will be updated in the dossier.

A safety risk assessment for potential process-related impurities included in the active substance process relative to patient safety was performed. The sources of the impurities are sufficiently addressed.

The safety risk assessment strategy involves comparison of the theoretical worst-case concentration of impurities, assuming no removal, to calculated safety concern thresholds.

The worst-case levels of residual raw materials and reagents from the BNT162b2 active substance manufacturing process were calculated to be significantly below the pre-determined safety limits. This is found acceptable.

Characterisation

Analytical characterisation was performed on BNT162b2 active substance manufactured at commercial scale. This is found acceptable.

The physico-chemical characterisation involved primary structure, 5' cap structure, poly(A)tail and higher order structure evaluation. Primary structure was confirmed by oligonucleotide mapping and the orthogonal method, RNA sequencing using Next Generation Sequencing (NGS) technology. The results confirm the RNA sequence. The 5'-cap and 3' poly A tail were confirmed by two separate LC-UV/MS-methods. It was demonstrated that the predominant form of the 5' terminus is the full-length nucleotide sequence with the 5'-Cap. The higher order structure of BNT162b2 mRNA active substance was characterised in solution using biophysical techniques.

Overall, state-of-the-art methods were applied for physico-chemical characterisation and the results confirmed the expected sequence and quality attributes. It is recommended that the applicant should comprehensively describe the capability of a specific analytical method to detect lower amounts of product related impurity in the presence of the correct form in the active substance. **(REC9)**.

An uncertainty in the characterisation section is that no biological characterisation is presented. In response to questions during the procedure, the applicant has committed to update dossier with the strategy for potency determination and to address relevant functional assays including the in vitro expression (potency) results and results from the analysis of expressed protein size for active substance lot 20Y513C101. It is recommended that the applicant should discuss the results and the assay suitability for a certain method used for biological characterization of protein expression for the active substance **(REC10)**.

As described above, the expressed protein size results are currently not sufficiently confirmed and a specific obligation is laid down in the terms of the MA requiring their adequate characterisation **(SO1)**.

Process-related and product-related impurities as well as potential contaminants are described. A number of batches were evaluated for impurities, i.e. clinical, initial emergency supply and PPQ batches from both manufacturing sites.

The sole product-related impurity addressed is double-stranded RNA, derived from the in-vitro transcription reaction. Results from the active substance batches demonstrate that the level of double stranded RNA is low, acceptable and consistent.

In addition to double stranded RNA, there are truncated RNA, also referred to as fragmented species. Truncated RNA is reflected in the AS specification in terms of RNA integrity. However, the characterisation of BNT162b2 AS is currently not found to be complete in relation to a specific parameter. This is especially important considering that the current AS and finished product acceptance criteria allow for a proportion of fragmented species. The Applicant should provide additional data to further characterise the truncated and modified mRNA species present in the finished product. Relevant protein/peptide characterization data for predominant species should be provided **(SO1)**.

Residual DNA template is a process-related impurity derived from the linearised DNA template added to the in-vitro transcription reaction. Residual DNA template is measured as defined in the active substance specification. The levels are controlled by a specification limit which is considered suitably low.

The potential contaminants described in this section are endotoxin and bioburden. Acceptable results are shown for the Proteinase K pool, UF retentate pre recovery, UF-product pool and the active substance, for all batches investigated.

Specification

The active substance specifications contain tests for appearance (clarity, coloration (Ph. Eur.)), pH (Ph. Eur.), content (RNA Concentration) (UV Spectroscopy), Identity of Encoded RNA Sequence (RT-PCR), RNA Integrity (Capillary Gel Electrophoresis), 5'- Cap (RP-HPLC), Poly(A) Tail (ddPCR), Residual DNA Template (qPCR), dsRNA (Immunoblot), Bacterial Endotoxin (Ph. Eur.) and Bioburden (Ph. Eur.).

The proposed specification for active substance is considered acceptable for authorisation with respect to the attributes chosen for routine release testing. During the procedure the specification limits for a number of attributes were tightened in response to questions.

The length of the poly(A) tails in BNT162b2 active substance is important for RNA stability and translational efficiency and even though comparable results have been reported to date, the poly(A) tail length should be included to the active substance release testing **(SO2)**.

The rationale used to establish the acceptance criteria is described in detail and based on a limited data set representative of BNT162b2 active substance manufactured at the intended commercial scale and process. From the available data, mRNA integrity, dsRNA and Poly(A) tail acceptance criteria are considered in relation with batches used in clinical studies and with the demonstrated manufacturing capability and need to be re-assessed and revised as appropriate as further data becomes available **(SO2)**.

Potency testing is not included in the control of active substance but instead is performed at the level of finished product release testing. Considering the nature of this product, the approach is endorsed by the CHMP.

Analytical methods

All analytical methods used for testing of the active substance are sufficiently described in the dossier. The following tests are performed in accordance with Ph Eur chapters; clarity (Ph Eur 2.2.1), colour (Ph Eur 2.2.2), pH (Ph Eur 2.2.3), bacterial endotoxins (Ph Eur 2.6.14) and bioburden (Ph Eur 2.6.12).

All non-compendial analytical methods are sufficiently described. These analytical methods were suitably validated against the parameters presented in ICH Q2(R1).

The technical procedure for the quantification of the poly(A) tail is considered, in general, sufficiently described but the suitability of this method for the intended purpose remains to be confirmed **(SO2)**.

Batch analysis

Batch results are presented for active substance batches used for nonclinical toxicology, clinical trials, process performance qualification (PPQ), emergency supply and stability.

In general, the results obtained using the commercial process (Process 2) demonstrate batch to batch consistency with a few exceptions.

Reference materials

The current reference standard is referred to as the Clinical Reference Material (CRM). A stability protocol is provided. The Applicant has agreed to provide additional information such as protocol on preparation and qualification on the future reference material, as requested **(REC12)**.

In future, a two-tiered system for future commercial reference material will be implemented. A primary reference material (PRM) and an initial working reference material (WRM) will be established for the active substance reference material.

Container closure

The information regarding container closure system is acceptable. Compliance with Ph. Eur. has been verified.

Stability

Based on the limited stability data presented a shelf-life at -20 ± 5°C can be approved for the active substance when stored in the commercial container closure system. The stability program is designed to follow ICH guidelines. The test methods used are stability indicating. Data from the sites Andover, Mainz, Rentschler are included.

It is noted that the Applicant states that testing is currently in progress on the clinical batches and the dossier will be updated with data for these batches, as well as any new data available for the primary process validation batches. Thermal cycling studies have been initiated and a minimum of one process validation batch will be subjected to photostability studies at a future date.

Based on the stability data presented a shelf-life at -20 ± 5°C can be approved for the active substance when stored in the commercial container closure system.

2.2.3. Finished Medicinal Product

Description of the product and pharmaceutical development

The BNT162b2 finished product (FP) is supplied as a preservative-free, 5 dose multidose concentrate to be diluted prior to intramuscular injection. The finished product is a sterile dispersion of RNA-containing lipid nanoparticles (LNPs) in aqueous cryoprotectant buffer.

Each vial, containing 0.45 mL of the finished product at pH 6.9 - 7.9 is designed to deliver a total of 5 doses after dilution by addition of 1.8 mL of sterile 0.9% sodium chloride solution to a total volume of 2.25 mL. Each dose contains 30 µg of RNA in 0.3 mL.

The overfill in the vial is required to ensure that the full five doses can be removed from the multi-dose vial after dilution and correctly administered, taking account of potential loss of product during these dilution and administration steps. The justification for the overfill is sufficiently discussed and considered to be acceptable. The applicant development data and finished product testing confirm that 5 doses can be consistently extracted from the vial and delivered after dilution.

The finished product is supplied in a 2 mL glass vial sealed with a bromobutyl rubber stopper and an aluminum seal with flip-off plastic cap.

The full list of excipients is listed above in section 2.2.1; ALC-0315 and ALC-0159 (functional lipids), DSPC and cholesterol (structural lipids), potassium chloride, potassium dihydrogen phosphate, sodium

chloride and disodium phosphate dihydrate (buffer components), sucrose (cryoprotectant) and water for injections.

All excipients except the functional lipids ALC-0315 and ALC-0159 and the structural lipid DSPC comply with Ph. Eur. The functional lipid excipients ALC-0315 and ALC-0159, are classified as novel excipients. Both structural lipids DSPC and cholesterol are used in several already approved finished products. A justification was provided for why DSPC is not considered to be a novel excipient. DSPC is used as part of the LNP for the EU approved finished product Onpattro which is administered intravenously in a much higher dose than the intramuscular dose for this product. Additionally; DOPC, a structurally related lipid, is present in finished products approved in the EU for intramuscular administration. It was therefore concluded that the level of information provided for DSPC, is in line with the requirements for a known excipient are sufficient and appropriately justified.

The vial, stopper and seal components are compliant with the appropriate Ph. Eur. monographs for primary containers and closures.

Formulation development

The section on formulation development describes and justifies the chosen formulation and is sufficiently comprehensive.

The formulation development studies of the RNA containing lipid nanoparticles have been thoroughly described. The LNPs consists of four lipids, each has a functional or structural purpose. The formed RNA-containing LNPs are solid particles. Furthermore, the accumulated batch-data to date show consistent manufacture of lipid nanoparticles both with respect to size and polydispersity.

Lipid-related impurities have been identified in the finished product and have been characterized. An investigation has been initiated and is ongoing to assess and review potential root causes. The outcome of the investigation shall be provided (SO2).

Visual particulate matter has occasionally been observed in finished product batches. Characterization data have been presented and the control strategy has been discussed. The data demonstrates that the particles are comprised of components of the finished product formulation. A 100% visual inspection is performed during manufacturing and the automatic inspection system is updated to improve the inspection. Routine release or routine stability data indicate that the propensity of particles to form following storage is low. If particles are observed in the diluted vaccine the vial should be discarded.

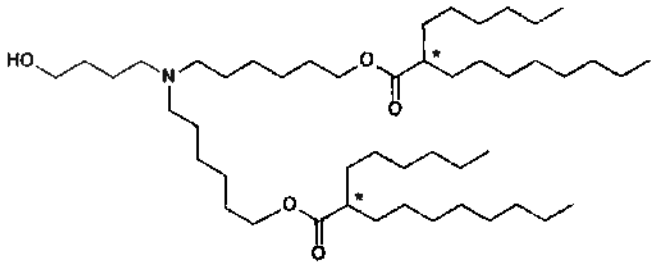
Novel excipients

Two novel excipients are included in the finished product, the cationic lipid ALC-0315 and the PEGylated lipid ALC-0159. Limited information regarding the novel excipients are provided.

ALC-0315 (cationic lipid)

The ALC-0315 novel excipient is a cationic lipid containing a tertiary amine and two ester moieties, ((4-hydroxybutyl)azanediyl)bis(hexane-6,1-diyl)bis(2-hexyldecanoate).

Figure 1 ALC-0315 structure



Asterisks (*) indicate chiral centers.

A brief description of the chemical synthesis is provided. The suppliers are defined in the dossier. A similar manufacturing process is used for ALC-0315 in clinical and commercial finished product batches.

In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the applicant should provide additional information about the synthetic process and control strategy for the excipient ALC-0315. (**SO4**)

The proposed specification is considered acceptable based on the available data. However, additional information regarding specifications that should be provided **(SO4).**

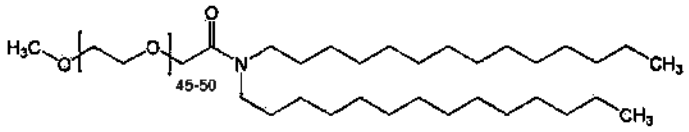
Stability data from one supplier indicate that ALC-0315 is stable when stored at the recommended storage conditions. Additionally, the excipient is stable at room temperature suitable for use in further manufacturing steps. Stability data from one supplier is considered representative for lipid from another supplier.

Lipid related impurities have been observed in some recently manufactured finished product batches, correlated with ALC-0315 lipid batches. The quality of ALC-0315 excipient is considered acceptable based on the available data on condition that specific impurities in the finished product will be further evaluated **(SO2).**

ALC-0159 (PEGylated lipid)

The ALC-0159 novel excipient is a PEGylated lipid, 2 [(polyethylene glycol)-2000]-N,N-ditetradecylacetamide.

Figure 2 ALC-0159 structure



A brief description of the chemical synthesis is provided.

The suppliers are defined in the dossier. The same supplier was used during development for clinical phase 1, 2 and 3 studies. The same synthetic route was used for ALC-0159 throughout development of the finished product.

In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the applicant is requested to provide additional information about the synthetic process and control strategy for the excipient ALC-0159. **(SO5)**

The proposed specification is considered acceptable based on available data. However, in order to improve impurity control strategy and to ensure batch to batch consistency of the finished product, there are additional information regarding specifications that should be provided **(SO5)**.

Stability data indicate that ALC-0159 is stable when stored at the recommended storage conditions.

Manufacturing process development

The development history of the finished product is sufficiently described. The process has been transferred to commercial facilities for manufacture of later clinical materials, emergency supply and commercial supply. A table on finished product lot genealogy and usage has been provided.

The applicant states that comparability is demonstrated in a stepwise approach through a combination of release testing and extended characterization methods. It is agreed that comparability was sufficiently demonstrated with only small differences noted.

During the present regulatory procedure, release testing results of a number of recently manufactured GMP-batches was presented. The release data for the GMP-batches are compared to the clinical batches as well as to the results of the emergency supply lots. It is agreed that the differences noted are few and minor for all tests included in the FP specification and that comparability has been sufficiently demonstrated subject to the specific obligations further described, for the attributes tested and given the pandemic situation. In addition, the comparison will be further extended with additional characterization testing on future batches of finished product. The applicant has confirmed that testing will be performed according to the agreed finished product comparability testing protocol and the results will be submitted in the frame of a specific obligation (**SO3**).

A concurrent validation approach will be used due to the urgent need for this product and the pandemic situation. The rationale for this approach has been documented and is agreed. This concurrent approach requires interim reports to be documented for each individual validation run. An overall report per site will be compiled that summarises all evaluations and contains a comparability assessment of the data of all batches manufactured. Finally, a concluding report linked to this plan will be written that summarises all findings from the different validation reports. Process validation (PPQ) for commercial scale batches were initiated, and a summary report from one PPQ validation batch was provided.

In summary, given that an acceptable validation program at the commercial facility has been established, and a summary report from one PPQ validation batch was provided, the information on process validation is considered acceptable subject to the agreed specific obligation that the MAH should provide additional validation data (**SO3**).

The development of the manufacturing process is extensively described, and critical process parameters are defined. Process characterisation studies using scale-down models of individual unit operations, were performed.

Overall control strategy was presented but some parameters and ranges may be updated after PPQ and additional characterization studies completed. As for assessment of overall control strategy, a complete set of data and information is needed, this document will be assessed when finalised. A time-plan for the provision of the final data set has been agreed with the applicant **(SO3)**.

The analytical testing strategy of finished product has changed throughout the development and these changes have been described. Bridging studies have been performed for analytical tests that have been changed or replaced (subvisible particles, identity of encoded RNA sequence and RNA integrity). This is found acceptable.

Container closure system

The development of the container closure system is sufficiently presented. The primary packaging is composed of glass vial and rubber stopper and are compliant with the compendial requirements of Ph. Eur.

Controlled extraction studies have been performed on the bromobutyl rubber stopper. The applicant will provide the updated results from the leachables study for assessment. (**REC13**)

Microbiological attributes

Container closure integrity testing has been performed to demonstrate that the 2 mL container closure presentation is integral.

In order to improve the control strategy, the MAH should provide validation results of alternative sterility test i.e. rapid sterility test for assessment before implementation (**REC14**).

Compatibility

The studies described have been performed to assess physicochemical stability of the FP after dilution with 0.9% sodium chloride solution in the original glass vial as well with commonly used commercially available administration components and using worst-case conditions for dosage and administration in the clinical setting. The thawed hold time (in-use period) of undiluted finished product has been defined as 5 days at 2-8 °C and 2 hours at up to 30 °C.

Results presented support physicochemical stability of FP diluted in 0.9% sodium chloride solution for up to 24 hours at ambient or refrigerated temperatures (2-30°C) following an in-use thawed hold time of up to 5 days at 2-8 °C and 2 hours at 30 °C.

Compatibility with dosing components (syringes and needles) has been established for up to 6 hours. Furthermore, a microbiological in-use hold time study has been performed by a challenge test including five compendial micro-organisms. No significant growth (>0.5log10 from the start-point) was observed for any of the microorganisms within 12 hours of inoculation with storage at 20-25°C of diluted FP in 0.9% sodium chloride solution. Therefore, based on the results from the microbiological in-use hold time study, the proposed in-use period for up to 6 hours at ambient temperatures is agreed, as reflected in the product information. Furthermore, it is also stated by the applicant that the in-use period is in alignment with the WHO policy on the use of opened multi-dose vaccine vials (WHO Policy Statement: Multi-dose vial policy (MDVP) – handling of multi-dose vaccine vials after opening, rev 2014).

The compatibility of finished product is acceptably demonstrated by the dilution and administration simulation studies performed.

Manufacture of the product and process controls

The finished product is batch released by Pfizer Manufacturing Belgium NV, Puurs, Belgium or BioNTech Manufacturing GmbH, Mainz, Germany. The GMP status of the manufacturing and testing sites of the finished product have been confirmed.

The finished product manufacturing process includes the following main steps: active substance thawing and dilution, LNP formation and stabilisation, buffer exchange, concentration and filtration, concentration adjustment and addition of cryoprotectant, sterile filtration, aseptic filling, visual inspection, labelling, freezing and storage. Critical manufacturing steps are discussed, and relevant in-process controls are applied.

Dossier should be updated to provide more details on increase batch size including range number of AS bag and batches used, configuration of filters filter surfaces used and process controls (**REC14**). The absence of a test for residuals is considered acceptable.

Shipping validation

This section gives a summary of the qualification of the shipping process for transport of BNT162b2 finished product by passive thermal shipping containers for air and road shipments at temperature conditions of -90 to -60 °C from the finished product manufacturing and packaging site to dosing sites in the EU.

Short periods of time outside of the intended routine shipping condition of -90 to -60 °C during transport and at distribution sites have been defined.

The shipping temperature range of -90 to -60 °C is based on available stability data.

One thaw and refreeze cycle is allowed during transportation. Time during transportation out of the intended storage and shipping temperature range (-90 to -60 °C) without thaw is allowed for specified times and conditions for multiple transfers and redistribution during shipping with subsequent refreezing to -90 to -60 °C between transfers. The temperature excursion allowances are supported by data.

The selected shipping methods include shipping containers designed to maintain product temperature through a combination of insulation and dry ice. The applicant has prior experience with these passive thermal conveyances and has demonstrated that they maintain the -90 to -60 °C temperature range during product shipments, including minor shipping delays and short exposures to extreme temperatures occasionally observed during shipping and handling.

All shipments are continuously monitored using temperature data loggers.

The overall qualification strategy considered both thermal and mechanical aspects of shipping in passive thermal conveyance, supported by operational qualification and performance qualification testing. A summary of the shipping qualification strategy has been provided.

For the passive thermal conveyance, the qualification is focused on the ability of the passive system to maintain the required temperatures with specified phase change materials or dry ice when exposed to ambient temperature profiles for worst-case season. These studies are carried out in laboratory chambers to simulate the summer as worst-case ambient profiles.

A simulated distribution study demonstrated finished product and package integrity after exposure to simulated distribution hazard conditions, following the durations outlined in the worst-case extended transport lanes.

Results of thermal qualification have met specified acceptance criteria and support shipments of BNT162b2 finished product using the passive thermal conveyance shipping containers either directly or

via qualified distribution centres. Passive thermal conveyance performance qualification and the simulated shipping study finished product impact testing have been performed to complete shipping qualification assessing both thermal and mechanical aspects of shipping.

Process parameters for storage and shipping are found acceptable.

Media fills

Media fills have been performed for the filling line to validate the aseptic filling process and were run in accordance to guidelines. Results have been provided from three consecutive simulation studies and gave satisfactory results without any contaminated units. Results for the media fill cover the maximum process time for the manufacturing of finished product and simulate worst-case manufacturing conditions. The media fill validation demonstrated that aseptic conditions are maintained during the filling process. For the filling line, the maximum time will be established upon completion of media fill qualification studies. This is found acceptable.

Verification of in-process test methods

Data on verification of in-process test methods was pending at the time of the present regulatory procedure and should be provided during Q2 2021 (**REC15**).

Hold times

Hold times have been established. It is noted that any change of this section needs to be submitted to the Agency via a variation application.

Process validation plan

A FP process validation plan has been provided.

A concurrent validation approach will be used due to the urgent need for this product and the pandemic situation. The rationale for this approach has been documented. This concurrent approach requires interim reports to be documented for each individual validation run. An overall report per site will be compiled that summarises all evaluations and contains a comparability assessment of the data of all batches manufactured. Finally, a concluding report linked to this plan will be written that summarises all findings from the different validation reports.

It is described in the dossier that commercial scale PPQ-batches will be manufactured during Dec 2020 to Jan 2021 and the applicant has provided a process validation plan. In order to confirm the consistency of the finished product manufacturing process, the applicant should provide additional validation data, by March 2021. (**SO3**)

Filter validation

Acceptable information has been provided during the procedure for filter validation on the filters used for sterile filtration, describing the material, pore size and surface area. All study results met the predetermined acceptance criteria and the studies for microbial retention, membrane compatibility, extractable substances and integrity test determination have shown that the filters are appropriate for sterile filtration of the finished product. In addition, the applicant has clarified that the filter used for bioburden reduction is identical to the filters used for sterile filtration.

The MAH should provide the results for assessment from the filter validation as soon as they are available (**REC23**).

Control of excipients

ALC-0315 and ALC-0159 are novel excipients, not previously used in an approved finished product within EU. Additional information is provided separately in Section A.3 of the dossier.

DSPC is a non-compendial excipient sufficiently controlled by an in-house specification.

Cholesterol is sufficiently controlled according to the Ph. Eur. monograph with additional tests for residual solvents and microbial contamination.

The other excipients (sucrose, sodium chloride, potassium chloride, disodium phosphate dihydrate, potassium dihydrogen phosphate and water for injection) are controlled according to respective Ph. Eur. monograph.

The processing aids ethanol and citrate buffer are controlled according to Ph. Eur. standards and for HEPES and EDTA, reference is made to the active substance.

Product specification

The release and stability testing specifications for BNT162b2 finished product include tests for Appearance (Visual), Appearance (Visible Particulates), Subvisible Particles (Ph. Eur.), pH (Ph. Eur.), Osmolality (Osmometry), LNP Size (Dynamic Light Scattering), LNP Polydispersity (Dynamic Light Scattering), RNA Encapsulation (Fluorescence assay), RNA content (Fluorescence assay), ALC-0315 content (HPLC-CAD), ALC-0159 content (HPLC-CAD), DSPC content (HPLC-CAD), Cholesterol content (HPLC-CAD), extractable volume (Ph. Eur.), Lipid identities (HPLC-CAD), Identity of encoded RNA sequence (RT-PCR), Potency / in Vitro Expression (Cell-based flow cytometry), RNA Integrity (Capillary Gel Electrophoresis), Bacterial Endotoxin (Ph. Eur.), Sterility (Ph. Eur.) and Container Closure Integrity (Dye incursion). For all quality attributes tested on stability except for RNA integrity, the acceptance criteria for release and stability testing throughout shelf life are the same.

The specifications document for finished product in section 3.2.P.5.1 of the dossier includes a comprehensive panel of relevant tests along with corresponding acceptance criteria.

With the exception of osmolality, volume of injections in containers, HPLC-CAD (lipid identities) and RT-PCR (identity of encoded RNA sequence), which are performed only at FP release, all other analytical procedures are conducted at release and stability studies for finished product. It is stated by the applicant that the acceptance criteria used for stability during shelf-life will be the same as the acceptance criteria used for lot release.

Several questions in relation to the acceptance criteria in the FP specifications were raised during the procedure (i.e. the LNP size, polydispersity, RNA encapsulation, in-vitro expression and RNA integrity). The acceptance criteria were tightened.

For potency, RNA integrity, RNA encapsulation, lipid content and polydispersity index, the acceptance criteria will be re-assessed during Q2 2021 in order to ensure a consistent product quality by providing additional information to enhance the control strategy. This is found acceptable subject to a specific obligation. (**SO2**)

The vial contains an overfill in order to ensure that the full required volume (5 doses) can be delivered following dilution and administration in line with the product information. The finished product specification includes a test to confirm the extractable volume from the vial provides 5 doses. During the procedure the applicant proposed to update the product information and instructions for use to indicate that up to 6 doses can be delivered from the vial. This proposed change to the product information was not considered acceptable as no supporting data were provided to demonstrate that 6 doses can be consistently extracted. In order to support such a change in the product information, a variation should be submitted to update the specification limits for extractable volume, supported by appropriate pharmaceutical development data to support the claim of 6 doses (**REC21**).

A risk evaluation regarding the risk of N-nitrosamines impurities was provided concluding that there is no risk of the presence of nitrosamines in the finished product taking into account the active

substance, the finished product formulation and primary packaging. The risk assessment is considered acceptable.

It is recommended that a risk assessment should be provided with respect to the potential presence of elemental impurities in the active product based on the general principles outlined in Section 5.1 of ICH Q3D **(REC17)**.

A question was raised during the procedure since no information and discussion was provided in the dossier on lipid-related impurities originating from the degradation of the LNP. It is argued by the applicant that with respect to potential lipid-related impurities originating from the degradation of LNPs, no degradation of the LNP FP has been observed in the stability studies at the recommended storage temperature (-70 to -90 °C) for the LNP as shown by specifications for size and polydispersity, RNA encapsulation, RNA and lipid content and RNA integrity quality attributes. This is acknowledged. In addition, further evaluation of lipid-related impurities in the finished product should be performed and the results submitted and discussed in the frame of a specific obligation (**SO2**).

Analytical methods

The analytical methods used have been adequately described and (non-compendial methods) appropriately validated in accordance with ICH guidelines.

Batch analysis

The dossier includes release testing results of four recently manufactured GMP-batches. These finished product GMP batches were manufactured at the commercial FP manufacturing site. The release data for these GMP-batches are compared to min-max ranges of the small-scale clinical batches as well as to the results of the emergency supply lots. It is agreed that the differences noted are few and minor for all tests included in the FP specification. Therefore, it can be concluded that comparability has been sufficiently demonstrated for the attributes tested given the pandemic situation and considering that further data is to be provided in the frame of a specific obligation. In addition, the comparison will be further extended with additional characterization testing on future PPQ-batches of finished product. The applicant has confirmed that testing will be performed according to the finished product comparability testing protocol. and the results will be provided in the frame of specific obligation **(SO3)**.

Reference materials

The finished product reference materials is the same as for active substance.

Stability of the product

A shelf-life of 6 months for the finished product is proposed when stored at the recommended storage condition of -90°C to -60°C.

The applicant has provided stability results up to 6 months at -80 to -60°C of one clinical batch and up to 6 months of a non-clinical batch of finished product. Two weeks data are also provided for two emergency supply under recommended storage conditions. In addition, there are newly initiated stability studies on the recently manufactured GMP-batches as well as plans to initiate stability studies on the future PPQ-batches.

Stability data have also been provided at accelerated (-40°C to +5°C) and stressed (+25°C to +30°C) storage conditions.

The stability studies are performed in accordance with ICH Q5C (Quality of biotechnological products: Stability testing of biotechnological/biological products) and the same or representative container-

closure system are used in these stability studies as will be used for commercial batches. The test methods used are stability indicating.

Overall, the presented stability data indicate no signs of degradation, significant trends or changes in terms of quality at the recommended storage condition (-90 to -60°C).

The applicant has provided updated reports from the ongoing stability studies and the presented data are considered sufficient and in support of the shelf-life claim since comparability has been sufficiently demonstrated between commercial scale GMP batches and the small-scale clinical batches.

In addition, the initial in-use period for the thawed, undiluted vial is 5 days at 2-8°C followed by storage at up to 30°C for not more than 2 hours. This is found acceptable.

Chemical and physical in-use stability has also been demonstrated for 6 hours at 2°C to 30°C after dilution in sodium chloride 9 mg/mL (0.9%) solution for injection.

It is described that the future PPQ-lots will be enrolled in the stability program and the stability protocol has been defined in the dossier. This is acceptable; however, the applicant should commit to provide the 6 months stability data for the PPQ-batches for assessment as soon as they are available. (**REC20**). Notwithstanding requests for further stability updates, in accordance with EU GMP guidelines, any confirmed out-of-specification result, or significant negative trend, should be reported to the Rapporteur and EMA.

It has been clarified by the applicant that results on photostability testing studies will be provided for assessment (**REC19**).

It is recommended that the applicant should investigate the opportunities for an increased temperature at long term storage conditions for the finished product from -70°C to -20°C. In addition, the applicant should investigate the possibility to prolong the in-use storage time (before dilution) of 5 days at 2-8°C as well as the possibilities to extend the claims for transport conditions at 2-8°C **(REC22)**.

A shelf-life of 6 months for the finished product at -90 to -60°C is accepted.

Adventitious agents

Adventitious agents' safety evaluation has been provided for the AS manufacturing sites and for the finished product manufacturing site.

Reagents used in active substance manufacturing and in the establishment of the MCB and WCB are the only materials of animal origin used in the manufacture of BNT162b2. The applicant has identified contamination of the product by Transmissible Spongiform Encephalopathy (TSE) agents as the main theoretical risk associated with these ingredients and it is deemed of minimal risk.

Additional clarifications were requested and provided for a number of other materials.

Sufficient details on the aseptic validation filling and media fills have been provided. Furthermore, adequate testing for bioburden and endotoxin is performed at different stages of the manufacturing process. Therefore, no additional concerns are raised.

2.2.4. Discussion on chemical, pharmaceutical and biological aspects

During the procedure, a number of issues were highlighted relating to the GMP status of the manufacture of the active substance and of the testing sites of the finished product for the purpose of batch release, the comparability between clinical and commercial material and the absence of validation data on finished product manufactured at the commercial site. These issues were classified as Major Objections (MOs).

After further information was obtained from the sites and inspectors, questions regarding the manufacturing were addressed and manufacturing authorisations and GMP certificates are in place for all active substance and finished product manufacturing and testing sites.

Some of the proposed sites for batch control testing are currently located in the USA. The following time-limited derogation has been introduced as a condition to the MA:

'In view of the declared Public Health Emergency of International Concern and in order to ensure early supply this medicinal product is subject to a time-limited exemption allowing reliance on batch control testing conducted in the registered site(s) that are located in a third country. This exemption ceases to be valid on 31 August 2021. Implementation of EU based batch control arrangements, including the necessary variations to the terms of the marketing authorisation, has to be completed by the 31 August 2021 at the latest, in line with the agreed plan for this transfer of testing. Progress reports have to be submitted on 31 March 2021 and included in the annual renewal application'.

Additional data have been submitted by the applicant during the procedure in response to the other MOs and other questions raised.

Having considered the emergency situation and the quality documentation provided, the CHMP imposed some specific obligations (SOs) with clearly defined due dates (refer to Conclusions for details). In addition, the CHMP adopted some Recommendations (RECs) to be addressed by the Applicant.

In addition, it should be ensured that, in accordance with Annex I of Directive 2001/83/EC and Article 16 of Regulation (EC) No 726/2004, the active substance and finished product are manufactured and controlled by means of processes and methods in compliance with the latest state of scientific and technical progress. As a consequence, the manufacturing processes and controls (including the specifications) shall be designed to ensure product consistency and a product quality of at least shown to be safe and efficacious in clinical trials and shall introduce any subsequent changes to their manufacturing process and controls as needed.

Active substance

Overall, the information provided is satisfactory. However, certain information is still pending due to the very short time frame of product development and will either be updated in the dossier imminently or further addressed in specific obligations and other post-approval measures.

Information on the manufacturing process and process controls for the manufacturing sites Andover and BNT Mainz & Rentschler have been provided and are considered satisfactory.

Two active substance processes have been used during the development; Process 1 and 2. The major changes between AS Process 1 and 2 are: increased process scale, DNA template changed from a PCR template to linearised plasmid DNA, magnetic bead purification replaced with proteinase K digestion and UFDF steps. Based on the differences observed between batches manufactured by active substance Process 1 and 2 for the CQA mRNA integrity and lack of characterisation data, a MO was raised regarding comparability, characterisation and clinical qualification of the one proposed acceptance criteria. Biological characterisation of the active substance was limited, and additional data and discussion were requested to address functionality. Additional characterisation data for the active substance are to be provided to confirm the identities of the observed Western Blot (WB) bands obtained by the *in vitro* expression assay **(SO1).**

Truncated RNA species are regarded as product-related impurities and can be expected due to the principle of the in-vitro transcription reaction (i.e. directional polymerase activity) and (theoretical) hydrolysis during manufacturing. Analysis of RNase treated samples showed that all species detected

by the capillary gel electrophoresis (CGE)-based method are composed of RNA. Manufacturing consistency with respect to fragmented species has been sufficiently demonstrated.

There were some differences in truncated RNA species level, however further analyses revealed a comparable overall fragmentation profile among Process 1 and Process 2 active substance batches. Additionally, oligonucleotide mapping data demonstrated no significant differences observed between Process 1 and Process 2 active substance batches.

The company does not expect truncated transcripts formulated in the finished product to pose a safety or efficacy concern, as in their view no protein expression is expected from truncated transcripts. Further, clinical trials with process 1 material have not revealed major safety concerns to date. Truncated BNT162b2 RNA species lacking either the 5′ cap or the poly(A) tail are expected to be rapidly targeted for degradation in the cytoplasm or would show a decrease or loss of translation efficiency. Preliminary characterization data on isolated fragment species suggest that fragment species predominantly include the 5′-cap but lack the poly(A) tail, supporting the hypothesis that most fragments would arise from premature termination in the IVT reaction.

However, as the overall characterisation of the truncated species is still limited, additional analysis of truncated species, additional translated protein characterisation, additional characterisation of lipid-related impurities and potential lipid-RNA species should be provided to support that they are not impacting clinical performance in terms of safety and/or efficacy. The current specification allows for a certain level of truncated mRNA species to be present however data from recent batches have shown levels of truncated species below that level. No related safety issues have been identified in the clinical studies thus far in subjects who received vaccine containing up to a certain level of truncated species. Therefore, the current specification is considered acceptable subject to the submission of additional data in the frame of a specific obligation (**SO1**).

Based on available data, the proposed specification for active substance is acceptable with respect to the attributes chosen for routine release testing. However, the length of the poly(A) tails in BNT162b2 active substance is critical for RNA stability and translational efficiency and therefore should be introduced in active substance release testing in the frame of a specific obligation (**SO2**). Moreover, the active substance specification acceptance limits should be re-assessed and revised as appropriate, as further data become available from ongoing clinical trials and in line with manufacturing process capability (**SO2**).

It is noted that the Applicant states that testing is currently in progress on the clinical batches and data for these batches, as well as any new data available for the primary process validation batches, will be provided. Based on the limited stability data presented, a shelf-life is approved for the active substance.

Finished product

The finished product is a preservative-free, multi-dose concentrate to be diluted for intramuscular injection, intended for 5 doses. The finished product is a sterile dispersion of RNA-containing lipid nanoparticles (LNPs) in aqueous cryoprotectant buffer.

The formulation development studies of the RNA containing lipid nanoparticles have been thoroughly described including studies that were performed with available active substance, representative of the mRNA platform and included in the finished product.

The development of the manufacturing process is extensively described, and critical process parameters are defined.

The manufacturing process includes lipid nanoparticle fabrication and bulk finished product formulation followed by fill and finish, and the process has been acceptably described.

Comparability between the commercial finished product and the clinical finished product has been sufficiently demonstrated for the attributes tested and will be subject to a specific obligation.

Limited data on the finished product batches manufactured at the commercial facility (entire manufacturing process at the commercial site Pfizer, Puurs, at commercial scale, active substance from process 2) were presented. A process validation plan for PPQ lots has been provided.

A concurrent validation approach will be used due to the urgent need for this product and the pandemic situation. The rationale for this approach has been documented. This concurrent approach requires interim reports to be documented for each individual validation run. An overall report per site will be compiled that summarises all evaluations and contains a comparability assessment of the data of all batches manufactured. Finally, a concluding report linked to this plan will be written that summarises all findings from the different validation reports.

Further data was requested in order to conclude on the consistency of finished product manufacturing, to assure comparability between the commercial product with the product used in clinical trials, and to support the claimed finished product shelf-life and storage conditions. A process validation plan for PPQ lots has been provided. Process validation (PPQ) for commercial scale batches were initiated, and a summary report from one PPQ validation batch was provided.

In summary, given that an acceptable validation program, also comprising the commercial facility at Puurs, Belgium, has been established, and a summary report from one PPQ validation batch was provided, the information on process validation is considered acceptable subject to the agreed specific obligation that the MAH should provide additional validation data **(SO3).**

The specifications for finished product include a comprehensive panel of relevant tests along with corresponding acceptance criteria. Several issues in relation to the acceptance criteria in the finished product specifications were raised, i.e. the LNP size, polydispersity, RNA encapsulation, in-vitro expression and RNA integrity. Whilst FP specifications were subsequently amended and overall found to be acceptable, the acceptance limits should be re-assessed, and revised as appropriate, as further data becomes available from ongoing clinical trials and in line with manufacturing process capability (**SO2**).

Two novel excipients are included in the LNP. Complete information is not provided for both the cationic lipid ALC-0315 and the PEGylated lipid ALC-0159. In order to assure comprehensive control throughout the lifecycle of the finished product and to ensure batch to batch consistency, further information needs to be submitted regarding the synthetic process and control strategy in line with specific obligations **(SO4, SO5).**

Lipid-related impurities have been observed in some recently manufactured finished product batches. For the batches with lipid-related impurities the existing quality control parameters including RNA integrity remain unchanged.

Considering the above and the emergency situation, the characterisation of the active substance and finished product is considered acceptable, and the proposed specifications for RNA Integrity and 5'-Cap are considered to be scientifically justified and acceptable. Nevertheless, additional data to complete the characterisation of the active substance and finished product and additional clinical data from batches currently in use in ongoing clinical studies, are considered important to confirm the clinical qualification of these specifications. These data are requested to be provided as specific obligations to the applied conditional marketing authorisation **(SO1, SO2)**.

Efficacy, safety and immunogenicity was demonstrated using clinical batches of vaccine from Process 1. The commercial batches are produced using a different process (Process 2), and the comparability of these processes relies on demonstration of comparable biological, chemical and physical characteristics of the active substance and finished product.

The characterisation and control of active substance and finished product are limited in relation to critical quality attributes and impurities. The suitability of the analytical methods used for control of potency and poly(A) tail have not been fully demonstrated.

Data demonstrate the presence of significant amounts of truncated/modified forms of mRNA at somewhat higher levels in the batches manufactured with the commercial process as compared to material used in clinical trials. These forms are poorly characterised, and the limited data provided for protein expression do not fully address the uncertainties relating to the risk of translating proteins/peptides other than the intended spike protein.

The control strategy for active substance and finished product is important to guarantee acceptable quality and ensure batch to batch consistency of the finished product. Regarding the proposed control strategy, questions were raised both with regard to the suitability of the test methods used and the acceptance criteria for some tests.

Based on the above, the following uncertainties are considered to be of importance for the benefit-risk assessment:

- Truncated and modified RNA are present as impurities. Considering the low dose of mRNA (30 µg), the impurities are not considered a safety issue based on general toxicological principles. However, when present in the cell there is a possibility that aberrant proteins will be expressed with possibilities for unwanted immunological events. The risk of this occurring is considered low based on the following observations and considerations:
    - Such impurities were present in the vaccine used in the Phase 3 clinical trials with an acceptable safety profile. Although the lack of characterisation hinders a full comparability evaluation there is no indication that there would be important qualitative differences in the nature of these impurities.
    - The high levels of these impurities reflect the instability of RNA resulting in generation of RNA fragments both in the transcription step and thereafter. Based on electrophoretic data it appears that there is a diverse set of fragments. Although not confirmed, it is unlikely that these RNA molecules to a large extent would be mRNA molecules with intact 5'-cap and 3'-polyA.
    - The level of any individual aberrant mRNA species would in any way be magnitudes lower than the level of the intact mRNA and this would be mirrored by the level of protein expression. The amount of the protein would be expected to be too low to elicit an immune response. The spike protein is a highly immunogenic protein and immunodominance would also ascertain that the immune response to the aberrant protein would be non-significant.
- Lipid related impurities were observed in recently produced finished product batches. Based on the low dose (30 µg mRNA) it is considered that the amounts of these impurities are too low to be of toxicological significance.

2.2.5. Conclusions on the chemical, pharmaceutical and biological aspects

The quality of this medicinal product, submitted in the emergency context of the current (COVID-19) pandemic, is considered to be sufficiently consistent and acceptable subject to the specific obligations abovementioned.

In general, physicochemical and biological aspects relevant to the clinical performance of the product have been investigated and are controlled in an acceptable way. While the characterisation data still

need to be completed, the results of tests carried out indicate consistency of product quality characteristics, and these in turn lead to the conclusion that from a quality perspective the product is expected to have a satisfactory clinical performance.

The submitted information indicate that currently manufactured product batches are of a quality that is appropriate and sufficiently comparable to that of clinical development batches. However, to ensure that the quality of future batches will also remain appropriate and comparable to that of clinical development batches over the life cycle of the medicinal product a number of issues are expected to be addressed though fulfilment of specific obligations, within defined time frames.

The CHMP has identified the following specific obligations to address the identified quality development issues that may have a potential impact on the safe and effective use of the medicinal product, and which therefore are needed to achieve comprehensive pharmaceutical (quality) data and controls for the product. The specific points that need to be addressed in order to fulfil the imposed specific obligations are detailed below.

In addition, and in accordance with Article 16 of regulation (EC) No 726/2004, the MAH shall inform the Agency of any information which might influence the quality of the medicinal product concerned, such as any necessary tightening of the finished product specifications earlier than July 2021. This is also related to the general obligation to vary the terms of the marketing authorisation to take into account the technical and scientific progress and enable the medicinal product to be manufactured and checked by means of generally accepted scientific methods.

In the context of the conditional marketing authorisation, the applicant should fulfil the following specific obligations (SOs):

- SO1: In order to complete the characterisation of the active substance and finished product, the MAH should provide additional data. **Due date: July 2021. Interim reports: March 2021.**
- SO2: In order to ensure consistent product quality, the MAH should provide additional information to enhance the control strategy, including the active substance and finished product specifications. **Due date: July 2021. Interim reports: March 2021.**
- SO3: In order to confirm the consistency of the finished product manufacturing process, the MAH should provide additional validation data. **Due date: March 2021.**
- SO4: In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the MAH should provide additional information about the synthetic process and control strategy for the excipient ALC-0315. **Due date: July 2021, Interim reports: January 2021, April 2021.**
- SO5: In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the MAH should provide additional information about the synthetic process and control strategy for the excipient ALC-0159. **Due date: July 2021, Interim reports: January 2021, April 2021.**

As regards SO1, the following data are requested in order to complete the information on the active substance and finished product characterisation.

a) Additional data is to be provided to further characterise the truncated and modified mRNA species present in the finished product. Data are expected to cover batches used in clinical trials (for which the characterisation data could be available earlier) and the PPQ batches. These data should address results from ion pairing RP-HPLC addressing 5'cap levels and presence of the poly(A) tail. These data should further address the potential for translation into

truncated S1S2 proteins/peptides or other proteins/peptides. Relevant protein/peptide characterization data for predominant species should be provided. Any homology between translated proteins (other than the intended spike protein) and human proteins that may, due to molecular mimicry, potentially cause an autoimmune process should be evaluated. **Due date: July 2021. Interim reports: March 2021, and on a monthly basis.**

b) The analysis of the main peak of the RNA integrity test representing the full-length RNA, should be also undertaken addressing 5'cap levels and presence of the poly (A) tail. **Due date: July 2021. Interim report: March 2021**

c) Additional data for the active substance are to be provided to confirm the identities of the observed Western Blot (WB) bands obtained by the *in vitro* expression assay. Protein heterogeneity, resulting in broad bands on the WB and uncertainties in the theoretical intact molecular weight of the spike protein, is assumed to be due to glycosylation. Therefore, to further confirm protein identities, enzymatic deglycosylation of the expressed proteins followed by WB analysis should be performed. Correlation with the calculated molecular weights of the intact S1S2 protein should be demonstrated. **Due date: July 2021. Interim report: March 2021**

As regards SO2, the following data are requested to be provided in order to ensure a comprehensive control strategy, including active substance and finished product specifications:

a) The active substance and finished product specifications acceptance limits, should be re-assessed and revised as appropriate, as further data becomes available from ongoing clinical trials and in line with manufacturing process capability and stability data of the product. Comprehensive data should be provided comprising batch analyses of a suitable number of commercial batches as well as analyses of batches that have been used in the (ongoing) clinical trials. **Due date: July 2021, Interim reports March 2021, and on a monthly basis.**

b) Poly(A) tail length is considered a critical attribute, which should be controlled on each batch, even though comparable results were obtained until now. An active substance specification to control poly(A) length should be introduced. A suitable method should be developed and appropriate acceptance criteria should be set. **Due date: July 2021, Interim reports: March 2021**

c) The poly(A) tail percentage is considered a critical attribute, but uncertainties remain on the suitability of the method. Additional data should be provided to support the suitability of the method used for %poly(A) tail or an alternative suitable assay should be developed and introduced. The %poly(A) tail should be characterised following any future active substance process changes. **Due date: July 2021, Interim reports: March 2021**

d) Since mRNA integrity and polydispersity are CQAs for the efficacy of the medicinal product, the finished product acceptance criteria for these parameters should be revised as further data becomes available from ongoing clinical trials and in line with manufacturing process capability. **Due date: July 2021, Interim reports: March 2021.**

e) Additional data should be provided to support the suitability of the method used for potency determination or an alternative suitable assay for this purpose should be developed and introduced. Then the finished product acceptance criteria for potency should be revised accordingly. **Due date: July 2021, Interim reports: March 2021**

f) Lipid-related impurities should be further evaluated. An appropriate control strategy should be introduced, suitably justified and provided for assessment during Q2 2021. **Due date: July**

2021, Interim reports (LMS content in commercial FP batches, investigation results): March 2021, and on a monthly basis.

As regards SO3, the following data are requested to be provided in order to ensure batch to batch consistency and to complete the information on process validation of the finished product manufacturing process.

a) Full commercial scale finished product PPQ-batches will be manufactured at the commercial facility Pfizer Puurs, Belgium. The applicant should provide the summary report on the completed commercial scale process validation activities. **Due date: March 2021.**

b) The applicant should perform testing of future process validation-batches of finished product according to the extended comparability testing protocol and the results should be provided for assessment. **Due date: March 2021.**

As regards SO4, the data are requested to be provided regarding the synthetic process and control strategy for the excipient ALC-0315 in order to improve the impurity control strategy, assure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product.

a) A detailed description of the chemical synthesis of ALC-0315 (e.g. information on reagents and process conditions) should be provided. **Due date: January 2021**

b) Differences in the manufacturing process between two suppliers should be described and possible impact on impurity profile should be discussed **by July 2021. Interim report: January 2021**

c) Information and justification of quality control of starting materials (e.g. general synthetic route, supplier and specifications) and solvents should be provided. **Due date: July 2021, Interim report: January 2021**

d) Information and justification on critical steps and intermediates (including specifications) should be provided. **Due date: July 2021, Interim report: January 2021**

e) Specified impurities should be further evaluated and appropriate specification limits for individual impurities should be included when more data are available. Acceptance criteria for specified and un-specified impurities should be added to the specification for ALC-0315 and should also be evaluated during stability studies. **Due date: July 2021, Interim report: April 2021**

f) The specification limit for total impurities should be re-evaluated as more batch data becomes available and revised, as appropriate. **Due date: July 2021**

g) The specification limit for assay should be tightened based on the provided batch data to improve the quality control strategy of the finished product. **Due date: July 2021**

h) Detailed method validation reports for assay, impurities, and residual solvents for ALC-0315 should be provided. **Due date: July 2021**

i) Results of stability studies in accordance with ICH guidelines should be provided. **Due date: July 2021, Interim report: April 2021**

As regards SO5, the following data is requested to be provided regarding the synthetic process and control strategy for ALC-0159 in order to improve impurity control strategy, assure comprehensive control and batch-to-batch consistency throughout the lifecycle of the active product.

a) A detailed description of the chemical synthesis of ALC-0159 (e.g. information on reagents and process conditions) should be provided. **Due date: January 2021**

b) Information and quality control of starting materials (e.g. general synthetic route, supplier and specifications) and solvents should be provided. Relevant acceptance criteria for molecular weight and polydispersity should be included in the specification for the starting material carboxy-MPEG. **Due date: July 2021, Interim report: January 2021**

c) Information and justification of critical steps and intermediates (including specifications) should be provided. **Due date: July 2021, Interim report: January 2021**

d) The specification limit for assay should be tightened based on batch data in order to provide a more stringent quality control of the finished product. **Due date: July 2021, Interim report: April 2021**

e) Specified impurities should be further evaluated and appropriate specification limits for individual impurities should be included when more data are available. Acceptance criteria for specified and un-specified impurities should be added to the specification for ALC-0159 and should also be evaluated during stability studies. **Due date: July 2021, Interim report: April 2021**

f) The specification limit for total impurities should be re-evaluated as more batch data are available and revised, as appropriate. **Due date: July 2021**

g) Acceptance criteria for tetrahydrofuran should be added to the specification for ALC-0159, unless otherwise justified, as it is included as a solvent in step 2 of the synthesis. **Due date: January 2021**

h) Detailed method validation reports for assay, impurities and residual solvents for ALC-0159 should be provided. **Due date: July 2021, Interim report: April 2021**

i) Results of stability studies in accordance with ICH guidelines should be provided. **Due date: July 2021, Interim report: April 2021**

2.2.6. Recommendations for future quality development

In the context of the obligation of the Marketing Authorisation Holder (MAH) to take due account of technical and scientific progress, the CHMP recommends the following points for investigation:

Active substance

1. The MAH should implement relevant testing strategies to ensure an adequate microbiological control for the starting materials.
2. The MAH should implement a relevant testing strategy to ensure that HEPES (Pfizer) raw material, included in the formulation buffer of FP, is free from contaminating RNases.
3. The MAH should implement in-house functional activity analytical methods for release testing of enzymes used in the manufacturing process at all relevant manufacturing sites, by Q1 2021.
4. The MAH should reassess the specification for the linear DNA template purity and impurities. The Applicant has already agreed to supply these by Q2 2021.
5. The MAH should perform and document a gap analysis to identify any supplemental qualification needed to align the methods used for the DNA template control with ICH requirements. The gaps identified should be addressed either prior to transferring the methods to relevant sites or during the transfer activities.
6. The MAH should provide active substance process validation data regarding the finalised

indirect filter qualification assessment and the shipping validation between sites.

7. The MAH should provide the results of the studies performed to enhance the robustness of the DNase digestion step.
8. The MAH should tighten the low limits of the proven acceptable ranges for the target volumes for ATP and CTP, to the levels needed to ensure a sufficiently high mRNA integrity in the active substance manufacturing process.
9. The MAH should comprehensively describe the capability of the next generation sequencing technology platform to detect lower amounts of RNA species of alternative sequence in the presence of the correct, more abundant RNA for the active substance.
10. The MAH should discuss the results and the assay suitability for the cell-based flow cytometry and the western blot method used for biological characterization of protein expression for the active substance.
11. The MAH should provide a summary of the validation/verification status of the immunoblot analytical procedure used to detect double stranded RNA (dsRNA) in BNT162b2 active substance.
12. In order to improve the control strategy, the MAH should provide the protocol on preparation and qualification of future primary and working reference standards for the active substance.

Finished Product

13. The updated results from the finished product leachables studies should be provided for assessment.
14. In order to ensure batch to batch consistency of the finished product the MAH should expand the description of the manufacturing process with more details. (1) When the batch size is twice the original one, the range number of active substance bags and active substance batches to be thawed, and the number of mixers should be stated. (2) The MAH should confirm the configuration of filters used in finished product manufacture. (3) The surface area of the sterile filter should be adapted to the batch size, unless otherwise justified; (4) process control for RNA content prior to dilution is important, particularly if several runs of TFF are performed in parallel with batch sizes
15. Data on verification of in-process test methods should be provided for assessment during Q1 2021.
16. In order to improve the control strategy, the MAH should provide results of the validation plan phase 2 of the rapid sterility test for assessment before implementation.
17. A risk assessment should be provided with respect to the potential presence of elemental impurities in the active product based on the general principles outlined in Section 5.1 of ICH Q3D and Ph. Eur. monograph Pharmaceutical Preparations (2619). A summary of this risk assessment should be submitted. The risk assessment should cover all relevant elements and sources in accordance with the guideline. The summary must enable a quantitative comparison of observed or predicted levels with the PDE's given in the guideline. It should contain what is necessary to evaluate the appropriateness and completeness of the risk assessment, including any assumptions, calculations etc. made. The control strategy for elemental impurities should be justified based on the risk assessment.
18. The MAH should provide the protocol on preparation and qualification of future primary and working reference materials for finished product testing.
19. In order to provide further information regarding the stability of finished product, Results from photostability testing and temperature cycling studies of the finished product should be provided for assessment in Q1 2021.
20. The applicant should provide the 6 months stability data for the finished product process performance qualification batches for assessment as soon as they are available.
21. This applicant proposed change to the product information to indicate that up to 6 doses can

be delivered from the vial was not considered acceptable as no supporting data was provided. In order to support such a change in the product information, a variation should be submitted to update the specification limits for extractable volume, supported by appropriate pharmaceutical development data to support the claim of 6 doses.

22. The MAH should investigate the opportunities for an increased temperature at long term storage conditions for the finished product from -70 °C to -20 °C. In addition, the MAH should investigate the possibility to prolong the in-use storage time (before dilution) of 5 days at 2-8 °C as well as the possibilities to extend the claims for transport conditions at 2-8 °C.
23. The MAH should provide the results for assessment from the filter validation as soon as they are available.

2.3. Non-clinical aspects

GLP inspections

The pivotal toxicological studies are stated to be GLP compliant by the Applicant. There were some issues identified during the assessment with repeat-dose toxicity study #38166 regarding the documentation which have led to a study audit GLP inspection conducted by the local German GLP Compliance Monitoring Authority at the facility where the study was performed, in November 2020. All the answers to the issues were acknowledged by the CHMP. The Applicant gave also comments on these issues. In light of all the elements provided, the issues identified were considered resolved.

With regard to repeat-dose toxicity study #20GR142 the only major concern identified was resolved with the answers from the Applicant that were considered satisfactory by the CHMP.

2.3.1. Pharmacology

The pharmacology dossier is based on initial studies of the functionality of the BNT162b2 (V9) RNA-based product and the encoded SARS-CoV-2 P2 S protein as well as on supporting studies of SARS-CoV-2 P2 S protein structure. This is followed by characterisation of the humoral and cellular immune response in mouse and nonhuman primate upon immunization with BNT162b2 (V9) and ends up with a SARS-CoV-2 challenge study of BNT162b2 (V9) immunized nonhuman primates.

No secondary pharmacodynamic, safety pharmacology or pharmacodynamic drug interaction studies have been conducted with BNT162b2 due to the nature of the RNA-based vaccine product, which is according to applicable guidelines (WHO guideline on nonclinical evaluation of vaccines, WHO Technical Report Series, No. 927, 2005).

Mechanism of action

SARS-CoV-2 infects the body by the use of the Spike protein (S) to attach to specific cell surface receptors, of which the angiotensin converting enzyme 2 (ACE2) may constitute a major part, as recently suggested. In addition to the initial attachment to a host cell, the S protein is also responsible for viral envelope fusion with the host cell membrane resulting in genome release. Due to its indispensable role, the S protein is a major target of virus neutralizing antibodies and has become a key antigen for vaccine development. By immunisation with the modified RNA (modRNA) product BNT162b2, encoding for the S protein, the intention is to trigger a strong and relatively long-lasting production of high affinity virus neutralizing antibodies, which can act through blocking the S-protein and it's receptor-binding domain (RBD) interaction with host cell receptors but also by opsonisation mediated virus clearance. In addition, the immunisation with BNT162b2 is also intended to elicit a concomitant T cell response of the Th1 type, supporting the B cells responsible for the production of S-specific antibodies and cytotoxic T cells that kill virus infected cells.

The S protein is a trimeric class I fusion protein that exists in a metastable prefusion conformation before engaging with a target cell. BNT162b2 encodes a P2 mutant (P2 S) variant of S where two consecutive proline mutations have been introduced in order to lock the RBD in the prefusion conformation. In addition, BNT162b2 is nucleoside-modified by a substitution of 1-methyl-pseudouridine for uridine and thus its inherent adjuvant activity mediated by binding to innate immune sensors such as toll-like receptors (TLRs) 7 and 8, is dampened, but not abrogated. Furthermore, the structural elements of the vector backbones of the BNT162b2 are optimised for prolonged and strong translation of the antigen-encoding RNA.

The potency of the RNA vaccine is further optimised by encapsulation of the RNA into lipid nano particles (LNPs), which protects the RNA from degradation by RNAses and enable transfection of host cells after intramuscular (i.m.) delivery. The functional and ionizable lipid, ALC-0315, is identified as the primary driver of delivery as it allows the LNPs to have a neutral charge in a physiological environment to facilitate internalization; the endosomal environment exhibits a positive charge and therefore triggers the translocation of RNA into the cytosol (Midoux & Pichon, 2015; Hassett et al, 2019; Patel et al, 2019); ALC-0159 is included in the formulation to provide a steric barrier to: 1) facilitate the control of particle size and homogeneity during manufacturing and product storage, and 2) regulate the association of plasma and proteins with the LNP surface. The composition of the LNPs may also affect the distribution of injected BNT162b2. In addition, it cannot be excluded the LNP composition contributes to the overall immunogenicity.

Administration of LNP-formulated RNA vaccines IM results in transient local inflammation that drives recruitment of neutrophils and antigen presenting cells (APCs) to the site of delivery. Recruited APCs are capable of LNP uptake and protein expression and can subsequently migrate to the local draining lymph nodes where T cell priming occurs. In general, following endocytosis of LNPs, the mRNA is released from the endosome into the host cell cytosol (Sahay et al, 2010; Maruggi et al, 2019). The process of an RNA vaccine-elicited immune response has been demonstrated in both murine and nonhuman primate models (Pardi et al, 2015; Liang et al, 2017).

Primary pharmacodynamic studies

Primary pharmacodynamic studies in vitro

To confirm the functionality of the BNT162b2 (V9) RNA-based product, protein expression, transfection frequency from BNT162b2 and cell surface expression of the SARS-CoV-2 P2 S protein antigen was assessed. BNT162b2 (V9) transfection of HEK293T cells indicated SARS-CoV-2 P2 S was correctly expressed on the cell surface, as indicated by flow cytometry staining of non-permeabilized cells with an anti-S1 monoclonal antibody. In addition, the cellular localisation of expressed S1 protein was investigated. The S protein co-localized with an ER marker, as detected by immunofluorescence experiments in HEK293T cells expressing BNT162b2-RNA, suggesting the S protein is processed within the ER.

In a set of supportive studies, it was investigated whether BNT162b2 RNA encodes for an amino acid sequence that authentically express the ACE2 binding site (RBD). Recombinant P2 S was expressed from DNA encoding for the same amino acid sequence as BNT162b2 RNA encodes for. Flow cytometry staining with spike protein (S) binding agents, as human ACE2 and monoclonal antibodies known to bind to authentic S-protein all indicated an authentically presented P2 S protein and ACE2 binding site. Low nanomolar affinity of P2 S binding to ACE2 PD and B38 mAb was demonstrated with the use of biolayer Interferometry.

To further structurally characterize the P2 spike protein, a cryo-electron microscopy (cryoEM) investigation of purified P2 S, expressed from DNA, was conducted. The cryoEM revealed, according to

the Applicant, a particle population closely resembling the prefusion conformation of SARS-CoV-2 spike protein. By fitting a previously published atomic model on to a processed and refined cryoEM dataset, a rebuilt model was obtained showing good agreement with reported structures of prefusion full-length wild type S and its ectodomain with P2 mutations. In the prefusion state the RBD undergo hinge-like conformational movements and can either be in an "up" position (open for receptor binding) or in a "down" position (closed for receptor binding). Three-dimensional classification of the dataset showed a class of particles that was in the conformation one RBD 'up' and two RBD 'down". This partly open conformation represented 20.4% of the trimeric molecules. The remainder were in the all RBD 'down' conformation. Although potent neutralizing epitopes have been described when the RBD is in the "heads down" closed conformation, the "heads up" receptor accessible conformation exposes a potentially greater breadth of neutralizing antibody targets. It is concluded that antibodies to both the up and down conformations will potentially be formed upon immunisation with the P2 S encoding BNT162b2.

Primary pharmacodynamic studies in vivo

The humoral and cellular immune response following IM administration of BNT162b2 (V9) was investigated in mice and nonhuman primates. The choice and relevance of the mouse for pharmacological animal model studies was based on the in-depth knowledge about the suitability, dosing and immunization regimen of BALB/c mice for RNA-based vaccine development. Non-human primates were chosen as they are a higher-ordered species, more closely related to humans, which may better reflect immune responses in humans. The selection of rats as the toxicology test species is consistent with the World Health Organization (WHO) guidance documents on nonclinical evaluation of vaccines (WHO, 2005). The documents recommend conducting vaccine toxicity studies in a species which mounts an immune response to the vaccine. The Wistar Han (WH) rat developed an antigen-specific immune response following BNT162b2 vaccination.

Balb/c, females were immunized IM on day 0 with 0.2, 1 or 5 µg RNA/animal of BNT162b2 (V9), or with buffer alone (n=8). Blood samples were collected on Days 7, 14, 21 and 28 after immunization. The IgG antibody response to SARS-CoV-2- RBD or S1 was analysed by ELISA. Immunization with BNT162b2 induced IgGs that bound to S1 and RBD, as detected by ELISA, and on day 28 after immunization showed a binding affinity of KD 12 nM or 0.99 nM (geometric mean) respectively, as detected by surface plasmon resonance.

To further characterise the antibody response to BNT162b2 and its potential capacity to reduce SARS-CoV-2 infections, a pseudo virus type neutralization assay (pVNT) was used as a surrogate of virus neutralization since studies with authentic SARS-CoV-2 requires a BSL3 containment. The pVNT was based on a recombinant replication-deficient vesicular stomatitis virus (VSV) vector that had been pseudotyped with SARS-CoV-2 S protein according to published protocols. A dose-dependent increases in SARS-CoV-2-S VSV pseudovirus neutralizing antibodies were observed in sera from BNT162b2-immunized mice. On day 14, the difference of the group treated with 5 µg RNA compared to the buffer control was statistically significant ($p = 0.0010$). On days 21 and 28, the differences of the groups treated with 1 µg and 5 µg BNT162b2 compared to the buffer control were statistically significant. The relevance of the pseudovirus assay for authentic SARS-CoV-2 was not discussed. For technical reasons, it was not possible to determine a ratio of neutralizing to non-neutralizing antibodies.

Immunisation of mice with BNT162b2 also induced IFN-γ secreting cells of both the CD4+ and CD8+ T-cell subsets. This was shown by ELISPOT after *ex vivo* re-stimulation of splenocytes with an S-protein overlapping peptide pool Day 28 after immunization. Cytokine profiling was also carried out by Multiplex analysis of cytokine release from the Day 28 Splenocytes. High levels of the Th1 cytokines IFNγ and IL-2 but minute amounts of the Th2 cytokines IL-4, IL-5 and IL-13 were detected after re-stimulation with S but not RBD overlapping peptide mix. The much higher immune cellular responses

elicited against the S1 protein compared to the RBD domain could be explained by the presence of significantly more T cell epitopes in the larger full-length S peptide mix (in addition, S1 covers the RBD domain). It should be emphasized that cellular immune reactivity is much more important against S1 than against the RBD domain, where neutralizing antibodies are more important to the latter. In addition, an elevated secretion of TNFα, GM-CSF, IL-1β, IL-12p70 and IL-18 was recorded after re-stimulation. In order to characterize the immunophenotype of B-and T-cells appearing in lymph nodes from mice immunized with BNT162b2 (V9), B- and T-cell subsets in draining lymph node cells were quantified by flow cytometry 12 days after immunization. Higher numbers of B cells were observed in the samples from mice that received BNT162b2 compared to controls. That included plasma cells, class switched IgG1- and IgG2a-positive B cells, and germinal centre B cells. T-cell counts were elevated, particularly numbers of T follicular helper (Tfh) cells, including subsets with ICOS upregulation, which play an essential role in the formation of germinal centres (Hutloff 2015).

In the nonhuman primate (rhesus macaques) studies, BNT162b2 (V9) was shown to be immunogenic after intramuscular administration. The serum concentrations of both S1-binding and the SARS-CoV-2 neutralizing antibody titres were at least an order of magnitude higher after BNT162b2 immunization of rhesus macaques than for the panel of SARS-CoV-2 convalescent human sera. In this study, total antibody response is measured using a luminex assay and results expressed on U/ml and for the neutralization assay results are expressed in VNT 50.

Antigen specific S-reactive T-cell response after BNT162b2 immunization of the macaques was measured by ELISPOT and ICS. While S-specific T cells were low to undetectable in naïve animals, strong IFNγ but minimal IL-4 ELISpot responses were detected after the second 30 or 100 µg dose of the BNT162b2. Intra cellular staining (ICS) confirmed that BNT162b2 immunization elicited strong S-specific IFNγ producing T cell responses, including a higher frequency of CD4+ T cells that produced IFNγ, IL-2, or TNF-alpha but a lower frequency of CD4+ cells that produce IL-4. An S-specific IFNγ producing CD8+ T cell response was also recorded.

A challenge study in rhesus macaques was conducted as nonclinical proof of concept (PoC). Rhesus macaques share a 100% homology with the human ACE2 sequence that interacts with the RBD of the S protein. BNT162b2 (V9) immunized macaques were challenged with SARS-CoV-2 intra nasally and intratracheally 55 days after the second immunization with BNT162b2. Rhesus macaques were immunized on days 0 and 21, in order to align with the clinical vaccination regimen. Some other COVID-19 vaccine candidates have different prime-boost intervals, such as 4 weeks for both ChAdOx1 (Graham et al., 2020) and mRNA-1273 (Corbett et al., 2020). At the time of challenge, SARS-CoV-2 neutralising titres ranged from 260 to 1,004 in the BNT162b2 (V9)-immunized animals. Neutralising titres were undetectable in animals from the control-immunized and sentinel groups. The presence of SARS-CoV-2 RNA was monitored by nasal and oropharyngeal (OP) swabs and bronchoalveolar lavage (BAL). Viral RNA was detected in BAL fluid from 2 of the 3 control-immunized macaques on Day 3 after challenge and from 1 of 3, on Day 6. At no time point sampled was viral RNA detected in BAL fluid from the BNT162b2 (V9)-immunized and SARS-CoV-2 challenged macaques. The difference in viral RNA detection in BAL fluid between BNT162b2-immunized and control-immunized rhesus macaques after challenge is statistically significant (p=0.0014). From control-immunized macaques, viral RNA was detected in nasal swabs obtained on Days 1, 3, and 6 after SARS-CoV-2 challenge; from BNT162b2 (V9)-immunized macaques, viral RNA was detected only in nasal swabs obtained on Day 1 after challenge and not in swabs obtained on Day 3 or subsequently. The pattern of viral RNA detection from OP swabs was similar to that for nasal swabs. No signs of viral RNA detected vaccine-elicited disease enhancement were observed. The viral RNA levels between control-immunized and BNT162b2-immunized animals after challenge were compared by a non-parametric analysis (Friedman's test), and the p-values are 0.0014 for BAL fluid, 0.2622 for nasal swabs, and 0.0007 for OP swabs.

Despite the presence of viral RNA in BAL fluid from challenged control animals, none of the challenged animals, immunized or control, showed clinical signs of illness (weight change, body temperature change, blood oxygen saturation and heart rate). The Applicant concluded, the absence of clinical signs in any of the challenged animals, immunised or control, despite the presence of viral RNA in BAL fluid from challenged control animals, indicates that the 2-4 year old male rhesus monkey challenge model appears to be an infection model, but not a clinical disease model. However, a further investigation by lung radiograph and computerized tomography (CT) was conducted. Radiographic evidence of pulmonary abnormality was observed in challenged controls but not in unchallenged sentinels nor in challenged BNT162b2-immunized animals except for a CT-score signal in 1 of 6 pre infection and 2 out of six at Day 10/EOP in BNT162b immunised animals. The CT score signal was at the same level as the control at Day 10/EOP. No radiographic evidence of vaccine-elicited enhanced disease was observed.

Secondary pharmacodynamic studies

No secondary pharmacodynamics studies were conducted with BNT162b2, which is acceptable to the CHMP.

Safety pharmacology studies

No safety pharmacology studies were conducted with BNT162b2. The Applicant refers to that they are not considered necessary according to the WHO guideline (WHO, 2005). In addition, no findings on vital organ functions have been recorded in the repeat dose toxicology studies. Thus, the absence of safety pharmacology studies is endorsed by the CHMP.

Pharmacodynamic drug interactions studies

No pharmacodynamics drug interaction studies were conducted with BNT162b2. This is agreeable to the CHMP.

2.3.2. Pharmacokinetics

The applicant has determined the pharmacokinetics of the two novel LNP excipients ALC-0315 (aminolipid) and ALC-0159 (PEG-lipid) in plasma and liver as well as their elimination and metabolism in rats. Furthermore, the Applicant has studied the biodistribution of the two novel lipids (in rats) and the biodistribution of a LNP-formulated surrogate luciferase RNA in mice (IV), as well as the biodistribution of a [^{3}H]-Labelled Lipid Nanoparticle-mRNA Formulation in rats (IM).

No traditional pharmacokinetic or biodistribution studies have been performed with the vaccine candidate BNT162b2.

In study PF-07302048_06Jul20_072424, the applicant has used a qualified LC-MS/MS method to support quantitation of the two novel LNP excipients. The bioanalysis methods appear to be adequately characterized and validated for use in the GLP studies.

PK studies with the two novel LNP-excipients ALC-0315 and ALC-0159:

Wistar Han rats were IV bolus injected with LNP formulated luciferase-encoding RNA at 1 mg/kg and ALC-0315 and ALC-0159 concentrations at 15,3 mg/kg and 1,96 mg/kg respectively. ALC-0315 and ALC-0159 levels in plasma, liver, urine and faeces were analysed by LC-MS/MS at different time-points up to 2-weeks.

ALC-0315 and ALC-0159 were rapidly cleared from plasma during the first 24 hours with an initial t½ of 1.62 and 1.72 h, respectively. 24 hours post-dosing, less than 1% of the maximum plasma concentrations remained. A slower clearance rate was observed after 24 hours with ALC-0315 and ALC-0159 terminal elimination t½ of 139 and 72.7 h, respectively.

Following plasma clearance, the liver appears to be to major organ to which ALC-0315 and ALC-0159 distribute. The applicant has estimated the percent of dose distributed to the liver to be ~60% for ALC-0315 and ~20% for ALC-0159. The observed liver distribution is consistent with the observations from the biodistribution study and the repeat-dose toxicology, both using IM administration.

For ALC-0315 (aminolipid), the maximum detected concentration in the liver (294 µg/g liver) was reached 3 hours after IV injection. ALC-0315 was eliminated slowly from the liver and after 2-weeks the concentration of ALC-0315 was still ~25% of the maximum concentration indicating that ALC-0315 would be eliminated from rat liver in approximately 6-weeks. For ALC-0159 (PEG-lipid), the maximum detected concentration in the liver (15.2 µg/g liver) was reached 30 minutes following IV injection. ALC-0159, was eliminated from the liver faster than ALC-0315 and after 2-weeks the concentration of ALC-0159 was only ~0,04% of the maximum detected concentration. The applicant was asked to discuss the long half-life of ALC-0315 and its effect, discussion on the comparison with patisiran, as well as the impact on the boosts and post treatment contraception duration. The applicant considered that there were no non-clinical safety issues based on the repeat dose toxicity studies at doses (on a mg/kg basis) much greater than administered to humans; this was acceptable to the CHMP.

Both patisaran lipids showed an essentially similar PK profile in clinic with a strongly biphasic profile and long terminal half-lives. According to the applicant, it is difficult to further contextualize the pharmacokinetic data and therefore to understand the safety of these molecules, beyond consideration of dose. There is a large dose differential between the human BNT162b2 dose and the dose used in the toxicity studies (300-1000x) which provides an acceptable safety margin.

Moreover, according to the Applicant given the large difference in dose between the toxicity studies and the clinically efficacious dose (300-1000x), it is unlikely that the administration of a booster dose will lead to significant accumulation. Finally, the applicant is of the opinion that these results support no requirements for contraception. The CHMP found this position agreeable.

While there was no detectable excretion of either lipid in the urine, the percent of dose excreted unchanged in faeces was ~1% for ALC-0315 and ~50% for ALC-0159.

Biodistribution of a LNP-formulated luciferase surrogate reporter:

To determine the biodistribution of the LNP-formulated modRNA, the applicant did study distribution of the modRNA in two different non-GLP studies, in mice and rats, determined the biodistribution of a surrogate luciferase modRNA formulated with a LNP with identical lipid composition used in BNT162b2 (mouse study) or the biodistribution of a [3H]-Labelled Lipid Nanoparticle-mRNA Formulation (rat study).

The mouse study used three female BALB-c mice per group and luciferase protein expression was determined by *in vivo* bioluminescence readouts using an *In Vivo* Imaging System (IVIS) following injection of the luciferase substrate luciferine. The readouts were performed at 6h, 24h, 48h, 72h, 6d and 9d post IM injection (intended clinical route) in the right and left hind leg with each 1 µg (total of 2µg) of LNP-formulated luciferase RNA.

In vivo luciferase expression was detected at different timepoints at the injection sites and in the liver region indicating drainage to the liver. As expected with an mRNA product, the luciferase expression was transient and decreased over time. Luciferase signals at the injection sites, most likely reflecting distribution to the lymph nodes draining the injection sites, peaked 6h post injection with signals of

approximately 10 000 times of buffer control animals. The signal decreased slowly during the first 72 hours and after 6 and 9 days the signals were further weakened to approximately levels of 18 and 7 times the signals obtained from animals injected with buffer control.

The signals from the liver region peaked 6h post injection and decreased to background levels 48h after injection. The liver expression is also supportive of the data from the rat PK study and the findings in the rat repeat-dose toxicological study showing reversible liver vacuolation and increased γGGT levels.

The biodistribution was also studied in rats using radiolabeled LNP and luciferase modRNA (study 185350). The radiolabeling data, measuring distribution to blood, plasma and selected tissues, of IM injection of a single dose of 50 µg mRNA over a 48-hour period is considered more sensitive than the bioluminescence method and indicate a broader biodistribution pattern than was observed with bioluminescence. Over 48 hours, distribution from the injection site to most tissues occurred, with the majority of tissues exhibiting low levels of radioactivity.

Radioactivity was detected in most tissues from the first time point (0.25 h) and results support that injections site and the liver are the major sites of distribution. The greatest mean concentration was found remaining in the injection site at each time point in both sexes. Low levels of radioactivity were detected in most tissues, with the greatest levels in plasma observed 1-4 hours post-dose. Over 48 hours, distribution was mainly observed to liver, adrenal glands, spleen and ovaries, with maximum concentrations observed at 8-48 hours post-dose. Total recovery (% of injected dose) of radiolabeled LNP+modRNA outside the injection site was greatest in the liver (up to 21.5%) and was much less in spleen (≤1.1%), adrenal glands (≤0.1%) and ovaries (≤0.1%). The mean concentrations and tissue distribution pattern were broadly similar between the sexes. No evidence of vaccine-related macroscopic or microscopic findings were found in the ovaries in the repeat-dose toxicity studies (Study 38166 and Study 20GR142) and no effects on fertility were identified in the DART study.

Immunogenicity of a LNP formulated luciferase modRNA:

Activation of the innate immune system following IM injection of a LNP-formulated luciferase reporter RNA into mice was assessed in a Luminex-based multiplex assay were serum samples (day -1 (pre), 6 h and day 9) were tested for levels of the following chemokines and cytokines: MCP-1, MIP-1β, TNF-α, IFN-α, IFN- γ, IL-2, Il-6, IL-10, IL1-β, IP-10. The applicant tested 3 different LNPs, all formulated together with luciferase RNA. The results suggest that the LNP formulation used in BNT162b2 (LNP8) slightly increased levels of MCP-1, IL-6, and IP-10 at 6h post immunisation. All chemokine/cytokine levels dropped to background levels at day 9.

In addition to innate immune activation, LNP formulated luciferase modRNA was able to induce IFN-γ T-cell responses (when challenged with MHC I-specific luciferase peptide pools) measured in splenocytes isolated from the mice at day 9.The LNP formulated luciferase modRNA did not induce the formation of luciferase-specific IgGs as measured by ELISA.

In an additional hPBMC study (R-20-0357), overall, low levels of pro-inflammatory cytokines (TNF, IL-6, IFNγ, IL-1β) and low or medium levels of chemokines (IP-10, MIP-1β, MCP-1) were secreted when assayed in an exploratory *in vitro* reactogenicity assay using human PBMCs from three donors. IP-10, MIP-1b, MCP-1 were seen to be increased among donors, because of transfection of antigen presenting cells after infection.

Metabolism of the two novel LNP-excipients ALC-0315 and ALC-0159:

Metabolism studies were conducted to evaluate the two novel lipids in the LNP, ALC-0315 (aminolipid) and ALC-0159 (PEG-lipid). No metabolic studies were performed with the modRNA or the other two lipids of the LNP. Overall, it seems as both ALC-0159 and ALC-0315 are metabolised by hydrolytic

metabolism of the amide or ester functionalities, respectively, and this hydrolytic metabolism is observed across the species evaluated.

The metabolism of the novel excipients, ALC-0159 and ALC-0315, were examined *in vitro* using blood, liver S9 fractions and hepatocytes, all from mouse, rat, monkey and human. The *in vivo* metabolism was examined in rat plasma, urine, faeces, and liver from a rat pharmacokinetics study where a luciferase-encoding modRNA formulated in an LNP was used.

Metabolism of ALC-0315 appears to occur via two sequential ester hydrolysis reactions, first yielding the monoester metabolite followed by the doubly de-esterified metabolite. The monoester metabolite was observed *in vitro* in rat blood, monkey S9 fraction, and *in vivo* in rat plasma and rat liver. The doubly de-esterified metabolite was observed *in vitro* in mouse and rat blood; monkey liver S9 fraction; and *in vivo* in rat plasma, urine, faeces and liver. Subsequent metabolism of the doubly de-esterified metabolite resulted in a glucuronide metabolite which was observed in urine only from the rat pharmacokinetics study. Additionally, 6-hexyldecanoic acid, the acid product of both hydrolysis reactions of ALC-0315, was identified *in vitro* in mouse and rat blood; mouse, rat, monkey and human hepatocytes; mouse, rat and human liver S9 fractions; and *in vivo* in rat plasma.

ALC-0315 was stable over 120 min (>93% remaining) in liver microsomes and S9 fractions and over 240 min (>93% remaining) in hepatocytes in all species and test systems.

The primary route of metabolism for ALC-0159 appears to involve amide bond hydrolysis yielding *N,N*-ditetradecylamine. This metabolite was identified in mouse and rat blood as well as hepatocytes and liver S9 from mouse, rat, monkey and human.

ALC-0159 was stable over 120 min (>82% remaining) in liver microsomes and S9 fractions and over 240 min (>87% remaining) in hepatocytes in all species and test systems.

Excretion of the two novel LNP-excipients ALC-0315 and ALC-0159:

Excretion of the two novel lipids in the LNP, ALC-0315 (aminolipid) and ALC-0159 (PEG-lipid) was studied in the rat PK study. No excretion studies were performed with the modRNA or the other two lipids of the LNP which is considered acceptable by the CHMP.

While there was no detectable excretion of either lipid in the urine, the percent of dose excreted unchanged in faeces was ~1% for ALC-0315 and ~50% for ALC-0159. Since almost no unchanged ALC-3015 was detected in urine or faeces, metabolism may play a bigger role in the elimination of ALC-0315 than ALC-0159.

2.3.3. Toxicology

The toxicological dossier for BNT162b2 is based on a total of three pivotal toxicological experimental studies; two repeat-dose toxicity rat studies and one DART fertility-EFD rat study. The test substance in the repeat-dose toxicity studies is BNT162b2 (100 µg of variant 8 in one study (study 38166) and 30 µg of the clinically relevant variant 9 in the second study (study 20GR142)), which consists of a modified RNA in a lipid nanoparticle (LNP) formulation. The differences between the variants are due to codon optimization. The LNP contains four excipients whereof two are considered novel (ALC-0315 and ALC-0159).

Repeat dose toxicity

The two general/repeat-dose toxicity studies involved IM exposure of Han Wistar rats to BNT162b2 for a total of 17 days (three weekly administrations) followed by three weeks of recovery. Overall, the

study designs only included a single experimental group each with a variant of BNT162b2 (V8 or V9 variant), with no dose-response assessment or specific experimental groups for the LNP alone or its novel excipients. No test substance-linked mortality or clinical signs were observed (except a slight increase [<1C] in body temperature). No ophthalmological and auditory effects were found. The animal model of choice, the rat, has not been assessed in the pharmacological dossier but a limited absorption/distribution study has been conducted in pharmacokinetics dossier. Immunogenicity was assessed in the toxicology studies.

Body weight and food intake: Exposure generated a slight reduction of absolute BW statistically significant at D9 (-6.8% to -11.3%; BNT162b2 V8) alternatively a weak body weight increase reduction [BNT162b2 v9]. No changes in food intake were observed.

Gross pathology and organ weights: At 100ug BNT162b2 V8 and 30ug BNT162b2 V9, the tissue at the injection site was thickened/enlarged with oedema and erythema at the end of exposure in a reversible manner. The spleen was enlarged (reversible) with up to 60% for both vaccine variants and doses. There was also an enlargement of the draining and inguinal lymph nodes at 100ug (BNT162b2 V8). Overall, there were signs of a significant immune response which is likely linked to the test substance. There was a trend of slightly enlarged liver in females at 100ug (BNT162b2 V8) but not at 30ug (BNT162b2 V9).

Histopathology: At 100ug BNT162b2 V8, there were observations of various inflammatory signs at the injection site (e.g. fibrosis, myofiber degeneration, oedema, subcutis inflammation and epidermis hyperplasia). Also, there was inflammation of the perineural tissue of the sciatic nerve and surrounding bone in most rats at d17. The bone marrow demonstrated increased cellularity and the lymph nodes showed plasmacytosis, inflammation and increased cellularity. The spleen demonstrated increased haematopoiesis in half the animals at d17. The liver showed hepatocellular periportal vacuolation at d17 (fully reversed during recovery) which may be related to hepatic clearance of ALC0315. Histopathology assessment of 30ug BNT162b2 V9 generated similar results as 100ug BNT162b2 V8 although not on as extensive level (possibly due to a lesser dose). Minimal to moderate inflammation and oedema was observed at the injection site (usually resolved after ~3d). There was minimal to moderate increased plasma cell cellularity in the lymph nodes and germinal center cellularity plus hematopoietic cell cellularity in the spleen at d17 (reversible at end of recovery). There was minimal increase cellularity in the bone marrow. Reversible vacuolisation in the liver was also observed.

The Applicant explained that peri-portal liver vacuolization was observed in both pivotal studies but are not related to any microscopic evidence of liver/biliary injury in animals (cellular hypertrophy, inflammation) nor any clinical data from Phase 1 study. Vacuoles are considered by the Applicant to be a result of ALC-0315 accumulation in liver and not PEG.

A novel finding at 30ug was minimal extra-capsular inflammation in the joints at d17.

Moreover, increases in neutrophils, monocytes, eosinophils and basophils were observed in study 20GR142. For the Applicant, increases in neutrophils, monocytes, eosinophils and basophils observed in the Study 20GR142 were related to the inflammatory/immune response to BNT162b2 administration. Similar findings were also identified in Study 38166 in animals administered 100 µg BNT162b2. The applicant stated that the increases in eosinophils and basophils are a minor component of the inflammatory leukogram, which is dominated by increases in neutrophils. The applicant also informed that characterisation of large unstained cells was not conducted since the identification of these cells does not provide additional information. The CHMP found this agreeable.

Immunogenicity: Treatment of rats with 100 ug BNT162b2 V8 generated SARS-CoV-2 neutralizing titers (based on a vesicular stomatitis virus (VSV)-based pseudovirus neutralization assay) and IgG antibodies against the S1 fragment and the RBD (based on ELISA) in serum samples. Treatment of

rats with 30 ug BNT162b2 V9 generated SARS-CoV-2 neutralizing antibodies (not a pseudovirus neutralization assay).

Haematology: At 30ug BNT162b2 V9 and 100ug BNT162b2 V8, there was a moderate to strong reduction of reticulocytes (48-74%, not specified for V9) coupled to lowered red cell mass parameters (RBC, HGB, and HCT). There was a moderate to strong increase (>100%) in large unclassified cells [LUC], neutrophils, eosinophils, basophils and fibrinogen that may be related to the inflammatory/immune response. The changes were reversible. No effects on coagulation were observed for V8 whereas a slight increase in fibrinogen was observed with V8 and V9.

Clinical pathology: A very strong but reversible increase (>100%) in pro-inflammatory acute phase proteins in the blood (A1AGP, A2M) was seen with both 30ug BNT162b2 V9 and 100ug BNT162b2 V8. Also, indicative of pro-inflammation, a slight to moderate reduced albumin/globulin ratio was seen for both variants. V8 (100ug) exposure generated increased levels of γGT (>200%) and increased γGT enzyme activity and increased AST levels (+ ~19%). V9 (30ug) exposure led to slight to moderate increases in AST and ALP levels (+20-100%), possible indicative of liver effects but no changes in γGT levels. There were no changes in cytokine levels (IFNγ, TNFalpha, Il-1b, Il6, Il-10) after 100ug V8 exposure (not measured for V9). For 100ug V8, there were no changes measured in urine whereas there was a slight-moderate reduction in pH for 30ug V9.

Genotoxicity

No genotoxicity studies have been provided. This is acceptable as the components of the vaccine formulation are lipids and RNA that are not expected to have genotoxic potential.

The novel excipient ALC-0159 contains a potential acetamide moiety. Risk assessment performed by the Applicant indicates that the risk of genotoxicity relating to this excipient is very low based on literature data where acetamide genotoxicity is associated with high doses and chronic administration (≥1000 mg/kg/day). Since the amount of ALC-0159 excipient in the finished product is low (50 µg/dose), its clearance is high and only two administrations of the product are recommended for humans, the genotoxicity risk is expected to be very low.

Reproduction Toxicity

In the DART study, the test substances used were BNT162b1, BNT162b2 and BNT162b3, which were given to female rats twice before the start of mating and twice during gestation at the human clinical dose (30 µg RNA/dosing day). The test substances were administered intramuscularly (IM) to F0 female Wistar rats 21 and 14 days before the start of mating (M-21 and M-14, respectively) and then on Gestation Day (GD) 9 and GD20, for a total of 4 doses. A subgroup was terminated at GD21 and another (litter) group was terminated at PND21. SARS-CoV-2 neutralizing antibody titers were found in the majority of females just prior to mating (M-14), in most females and foetuses at the end of gestation (GD21), and in most offspring at the end of lactation (PND21). There was transient reduced body weight gain and food consumption after each dose. No effects on the estrous cycle or fertility index were observed. There was an increase (~2x) of pre-implantation loss (9.77%, compared to control 4.09%) although this was within historical control data range (5.1%-11.5%). Among foetuses (from a total of n=21 dams/litters), there was a very low incidence of gastroschisis, mouth/jaw malformations, right sided aortic arch, and cervical vertebrae abnormalities, although these findings were within historical control data. Regarding skeletal findings, the exposed group had comparable to control group levels of presacral vertebral arches supernumerary lumbar ribs, supernumerary lumbar short ribs, caudal vertebrae number < 5). There were no signs of adverse effects on the postnatal

pups (terminated at PND21). It is noted that there is currently no available data on the placental transfer of BNT162b2. This information is reflected in section 5.3 of the SmPC.

Local Tolerance

No dedicated local tolerance studies have been conducted; however the assessment of local tolerance was performed in repeat-dose toxicity studies. At 100ug BNT162b2 V8, there was mostly slight to moderate oedemas but in some cases severe oedema. The severity increased with the 2nd and 3rd injections. The data for 30ug BNT162b2 V9 exposure indicated less severe but similar effects.

2.3.4. Ecotoxicity/environmental risk assessment

In accordance with the CHMP Guideline on the Environmental Risk Assessment of Medicinal Products for Human Use (EMEA/CHMP/SWP/4447100 Corr 2), due to their nature vaccines and lipids are unlikely to result in a significant risk to the environment. Therefore, environmental risk assessment studies are not provided in this Application for Marketing Authorisation, which is considered acceptable.

2.3.5. Discussion on non-clinical aspects

Pharmacology

The proposed medicinal product is composed of a modRNA formulated with functional and structural lipids forming lipid nano particles (LNPs), the latter having the purpose to protect the modRNA from degradation and enable transfection of the modRNA into host cells after IM injection. The composition of the LNPs is likely to affect the distribution of injected BNT162b2. In addition, it cannot be excluded the LNP composition contributes to the overall immunogenicity (see also toxicology below).

The general immune activating mode of action of LNP-formulated RNA vaccines have been described in the literature. The administration of LNP-formulated RNA results in transient local inflammation that drives recruitment of neutrophils and antigen presenting cells (APCs) to the site of delivery. Recruited APCs are capable of LNP uptake and protein expression and can subsequently migrate to the local draining lymph nodes where T cell priming occurs. In general, following endocytosis of LNPs, the mRNA is released from the endosome into the host cell cytosol (Sahay et al, 2010; Maruggi et al, 2019). The process of an RNA vaccine-elicited immune response has been demonstrated in both murine and nonhuman primate models (Pardi et al, 2015; Liang et al, 2017).

Whether other cells than professional APCs may transiently express the vaccine derived spike protein and therefore from a theoretical point of view, as compared to SARS-CoV-2 infected cells, also could potentially be targets for previously primed spike protein reactive cytotoxic T cells, if present, is not known. However, no overt signs of such adverse pharmacological responses have been recorded in the repeat dose toxicity study or in the clinical trials. In the clinical trial, a second dose was administered to patients who had been immunologically primed by the first dose. Moreover, in the clinical trials it appeared around 270 patients that was shown to have been seropositive for SARS-COV-2 before vaccination. In these cases, the expression of the spike protein on host cells occurred in the presence of a primed immune response to the spike protein but no overt adverse pharmacological response has been observed. The low amount of vaccine product in a single dose may limit the distribution of modRNA/LNP mainly to the injection site and to migrating APCs. Due to the transient expression of the modRNA, no persistent expression is expected.

Regarding the structural and biophysical characterization of the modRNA, a schematic description shows that 5 different sequences are included in the BNT162b2, of which two being coding sequences.

Concerning the protein expression obtained from the V8 and V9 variants, specific immune responses (total IgG binding Ab + neutralizing Ab) were obtained at significant levels against the Spike S protein in animals with both variants (in mice and rats), indicating the efficiency of the *in vivo* expression of Spike S protein. An additional study was provided (R-20-0360) further demonstrating *in vitro* protein expression. Transfection efficiency, expression rate and cellular viability were analysed in HEK293T cells, upon transfection with different constructs (saRNA, uRNA, modRNA V8 and V9). HEK293T cells were efficiently transfected by both modRNA V8 and modRNA V9 with higher transfection rate for V9, but quite similar the expression rate by V8 and V9.

Although some of the structural and biophysical characterization of P2 S as a vaccine antigen has been provided, it was investigated in supportive studies based on P2S expressed from DNA and not the product modRNA. While it is not considered to be of critical importance for the assessment in this procedure, it still provides a scientific understanding supporting the nonclinical key studies of humoral and cellular immune response, including SARS-CoV-2 neutralizing antibodies, as well as SARS-CoV-2 challenge nonclinical PoC.

In-vivo pharmacodynamics: The humoral and cellular immune response following IM administration of BNT162b2 (V9) was investigated in mice and nonhuman primates and was based on the in-depth knowledge about the suitability, dosing and immunization regimen of BALB/c mice for RNA-based vaccine development. Nonhuman primates were chosen as they are a higher-ordered species, more closely related to humans, which may better reflect immune responses in humans. This is accepted but a more in-depth discussion on the suitability of these pharmacological animal models have not been provided (e.g. susceptibility for SARS-CoV-2 infection and similarity to COVID 19 disease; potential bias for Th1- or Th2-skewed responses has been well characterized for certain mice strains). Only single immunisation was conducted in mice, as compared to the clinical 2-dose regimen, which was adequate since only characterization of the immune response, but no challenge study was carried out in mice. Also, no or limited attention to the induction of long-term memory responses nor immunogenicity and protection in aged animals has been paid. That being said, the induction of virus neutralizing antibodies in both mice (VSV-SARS-CoV-2 S) and primates (SARS-CoV-2) indicated that BNT162b2 immunization has the potential to induce neutralizing antibodies also in humans. Thus, vaccination with modRNA is expected to induce robust neutralising antibodies and a concomitant T cell response to achieve protective immunity.

In mice, the immune response was assessed by single immunization only. Taking the phenotyping of B and T cells in aggregate, the data indicates a concurrent induction of SARS-CoV-2 S-specific neutralizing antibody titers and a Th1-driven T-cell response by immunization with BNT162b2 (this was also seen in nonhuman primates).

Concerning the nonhuman primate (rhesus macaques) studies, the applicant considers the human convalescent serum panel as an assessable benchmark to judge the quality of the immune response to the vaccine; this is accepted by the CHMP.

Concerning the characterization of the T cell responses, the Applicant suggests the S-specific IFNγ producing T cell responses, including a high frequency of CD4+ T cells that produced IFNγ, IL-2, or TNF-α but a low frequency of CD4+ cells that produce IL-4, indicates a Th1-biased response occurred after the BNT162b2 (V9) immunization. This reasoning appears acceptable to the CHMP. The role of such a Th1 biased response was put in the context of antigen-specific T-cell responses playing an important role in generation of antigen-specific antibody response as well as in elimination of infected cells to mediate protection against disease.

When immunised macaques were challenged with SARS-CoV-2, a clear and statistically significant effect was observed on reduced presence of viral RNA in bronchoalveolar lavage (BAL) and oropharyngeal (OP) swabs. A clear effect was also recorded by blinded X ray scoring of the lungs. A

protective effect is also evident in the CT score Day 3 after challenge, however at Day 10/EOP, there was a CT signal in 2 out of six BNT162b immunized monkeys at the same level as observed in the control group. That signal is of unclear significance since also in 1 out of 6 pre infection BNT162b immunized animals a similar CT-score signal was observed. During this time period the SARS-CoV-2 neutralizing GMT in the BNT162b2-immunised rhesus macaques continued to decrease but remained above the GMT of a human convalescent serum panel.

In conclusion of the preclinical pharmacology, the presented data, including immunogenicity, triggering of neutralizing antibodies and Th1 response and reduced presence of viral RNA in challenged animals as well as radiological lung parameters, provide support for the vaccination approach. Due to species differences in the immune system between animal model species and humans, the conclusion whether this candidate vaccine will be sufficiently effective in humans needs to be established in clinical studies.

Pharmacokinetic

Pharmacokinetic (regarding the two novel LNP excipients): The two novel lipid excipients play different roles in the formulation and have different pharmacokinetics. It is worth to notice that the lipid displaying a persistent kinetic over time in liver is ALC-0315.

ALC-0159 is comprised of a polyethylene glycol (PEG) headgroup (~2000 M.Wt.) attached to hydrophobic carbon chains (ie, the lipid anchor). ALC-0159 is present in BNT162 at a low mol% (<2 mol%), and therefore dose, relative to the other lipids. PEGylated lipid can exchange out of the LNP after administration, thus allowing the desired binding of endogenous proteins (eg, Apolipoprotein E) and removing the steric barrier that would otherwise restrict interactions of the LNP with target cells and proteins.

ALC-0315 is an ionizable aminolipid in BNT162b2 and is the most important lipid component for efficient self-assembly and encapsulation of the mRNA within the LNP, and for providing successful delivery of mRNA into target cells.

The PEG-lipid (ALC-0159) is designed to largely exchange out of the LNP after administration and before uptake into target cells, whereas the aminolipid (ALC-0315) is critical to the efficient intracellular delivery of the mRNA through endosomal uptake and release and must remain with the LNP.

ALC-0159 is much more hydrophilic, in large part due to the presence of the PEG molecule which is known to be a strongly hydrophilic molecule (Ma et al, 1990). Due to the more hydrophilic and essential neutral nature of this molecule, ALC-0159 has a much lower affinity for tissues and relative to ALC-0315 there will be freer compound available for redistribution from tissue to plasma; thus, elimination will be more rapid.

The Applicant pointed out that during the course of the 2-week pharmacokinetic study, liver concentrations of ALC-0315 fell 4-fold from their maximum value indicating that 75% of the material delivered to the liver was eliminated over this two-week period.

ALC-0315 has no known biology. In the absence of this 'biological relevance' the applicant used an estimation of >95% elimination of ALC-0315 to represent the essential elimination from the body. The elimination half-life of ALC-0315 in the liver following IV administration in the rat is approximately 6-8 days. These data indicate that 95% elimination of ALC-0315 will occur approx. 30-40 days following final administration in the rat.

Based on the understanding of the process involved in the terminal half-life, redistribution from tissues into which the lipid nanoparticle is delivered, a similar half-life and time to 95% elimination in human is expected (Mahmood et al, 2010). Examination of the scaling of the comparable lipids (PEG2000-C-DMG, DLin-MC3-DMA) in patisiran indicates that the half-life of these lipids appears to scale with a value approaching the typically used exponent for half-life (0.25). If this is the case for ALC-0315 we may

expect a half-life approximating 20-30 days in human for ALC-0315 and 4-5 months for 95% elimination of the lipid (Mahmood et al, 2010).

Both lipids showed an essentially similar PK profile in clinic with a strongly biphasic profile and long terminal half-lives.

Given the large difference in dose between the toxicity studies and the clinically efficacious dose (300-1000x), it is unlikely that the administration of a booster dose will lead to significant accumulation. This is noted by the CHMP.

Biodistribution: Several literature reports indicate that LNP-formulated RNAs can distribute rather non-specifically to several organs such as spleen, heart, kidney, lung and brain.

In line with this, results from the newly transmitted study 185350, indicate a broader biodistribution pattern with low and measurable radioactivity in the ovaries and testes. Given the current absence of toxicity in the DART data, the absence of toxicological findings in gonads in the repeat-dose studies and that the radioactivity in the gonads were low (below 0,1% of total dose), the current data does not indicate it to be a safety concern. The relative high dose used in the rats (500x margin to human dose based on weight) also supports a low risk from distribution to the gonads in humans.

RNA stability and kinetics are not expected to be the same for all RNAs and are influenced by the nucleosides of the RNA and although expression of the full-length spike (S) protein is expected to follow similar kinetics of that of the luciferase with a transient expression fading over time, it cannot be excluded that differences in stability/persistence of the signal could differ between the luciferase protein and the spike (S) protein.

In an additional hPBMC study (R-20-0357), low levels of pro-inflammatory cytokines (TNF, IL-6, IFNγ, IL-1β) and low or medium levels of chemokines (IP-10, MIP-1β, MCP-1) were secreted when assayed in an exploratory *in vitro* reactogenicity assay using human PBMCs from three donors. The Applicant underlines that no specific general trend in cytokine secretion can be observed, given variability among donors and based on the low numbers of donors in the experiment.

Toxicology

Although no extensive pharmacological assessment has been conducted in rat (only in mouse and non-human primate), the rat was used as a toxicological animal model in the repeat-dose toxicity studies. The positive neutralization assay results in the repeat-dose toxicity studies demonstrate that V8 and V9 generate an immune response in this species (i.e. SARS-CoV-2 antibodies), partially supporting the use of the rat as an animal model. Other SARS-CoV-2 immune responses in rat remain unclear. The immune responses, especially at the injection sites (e.g. oedema, erythema), seem to increase with each injection in the studies (n=3). There was a marked increase in acute phase proteins, fibrinogen and reduced albumin-globulin ratio (but no increase in cytokines with V8, unclear for V9). There was also a general increase in immune cells (LUC, neutrophils, eosinophils, basophils) and a decrease in red blood cell parameters (reticulocytes, RGB, HGB, HCT). The spleen was enlarged at both 30ug V9 and 100ug V9 and the draining and inguinal lymph nodes were enlarged mostly at 100ug (V8) but also in a few animals at 30ug (V9).

Systemic complement activation (which sometimes may be induced by liposomal drugs and biologicals and potentially result in hypersensitivity reactions) was not investigated as no signs indicative of such clinical manifestations were detected. An absence of dose-response designs in the studies increases the difficulty to interpret the effects. Overall, the V8 and V9 test substances invoked a strong but mostly reversible immune-linked response in rats after 17d exposure. Increases in neutrophils, monocytes, eosinophils and basophils were observed in study 20GR142. For the Applicant, increases in neutrophils, monocytes, eosinophils and basophils observed in the Study 20GR142 were related to the

inflammatory/immune response to BNT162b2 administration. Similar findings were also identified in Study 38166 in animals administered 100 µg BNT162b2. The applicant stated that the increases in eosinophils and basophils are a minor component of the inflammatory leukogram, which is dominated by increases in neutrophils. The Applicant also informed that characterisation of large unstained cells was not conducted since the identification of these cells would not provide additional information. The CHMP agreed with this position.

With regards to the vaccine components, only the whole formulation (modified RNA in LNPs) were used, so there is no toxicological data on the LNP alone or its specific novel excipients. The novel LNP components, these are not considered primarily as adjuvant substances.

No genotoxicity nor carcinogenicity studies have been provided. The components of the vaccine formulation are lipids and RNA that are not expected to have genotoxic potential.

The novel excipient ALC-0159 contains a potential acetamide moiety. Risk assessment performed by the Applicant indicates that the risk of genotoxicity relating to this excipient is very low based on literature data where acetamide genotoxicity is associated with high doses and chronic administration (≥1000 mg/kg/day). Since the amount of ALC-0159 excipient in the finished product is low (50 µg/dose), its clearance is high and only two administrations of the product are recommended for humans, the genotoxicity risk is expected to be very low.

As the pharmacokinetic distribution studies in rat demonstrated that a relatively large proportion - second to the levels at the injection site - of the total dose distributes to the liver (up to 18%, and far more than levels seen in spleen [<1.1%], adrenal glands [<0.1%] and ovaries [<0.1%]). While there was no severe pathogenesis in liver, there were some reversible functional hepatic and/or biliary effects with V8 and V9 (enlarged liver, vacuolation, strongly increased γGT levels at >200% and activity, minor-moderate increase in levels of AST and ALP) which may be linked to the LNP. The γGT changes were not observed with 30ug V9, which may be due to variant differences and/or, more likely, a lower dose. The applicant is of the view that the vacuoles are a result of primarily ALC-0315 accumulation in liver. It can be noted that ALC-0159 needs to be lost from the surface of the LNP to facilitate efficient uptake into target cells. At the same time, ALC-0315 is present in the LNP at a high mol% (50 mol%) relative to the other lipids in the BNT162 vaccine, suggesting that this lipid is more likely to be present within the cells (and possibly in the vacuoles).

The assessment of the data available as regards to the DART study shows that there is no clear adverse signs on fertility and early embryogenesis effects. There were no effects on the oestrous cycle in dams but there was an ~2x increase in pre-implantation loss (~9.77% vs 4.1% in controls) but these effects are within historical control data (5.1% to 11.5%) so these findings do not raise any specific concern. It can be noted that the choice of rat as an DART animal model is supported by means of the repeat-dose toxicity rat studies which demonstrates an immune response to the vaccine candidates [V8 and V9] and the publication of Bowman et al (2013; PUBMED ID [PMID] 24391099) that reports that foetal-maternal IgG ratios are relatively low during organogenesis but that these ratios approach 1 by the end of gestation in both rat and human.

2.3.6. Conclusion on the non-clinical aspects

The applicant sufficiently addressed other concerns raised to be granted MA from a non-clinical perspective.

The CHMP is of the view that non-clinical data reveal no special hazard for humans based on conventional studies of repeat dose toxicity and reproductive and developmental toxicity.

Some rats intramuscularly administered Comirnaty (receiving 3 full human doses once weekly, generating relatively higher exposure in rats due to body weight differences) developed some injection site oedema and erythema and increases in white blood cells (including basophils and eosinophils) which is consistent with an inflammatory response as well as vacuolation of portal hepatocytes without evidence of liver injury. All effects were reversible. These findings are described in SmPC section 5.3.

As per guidance, no genotoxicity nor carcinogenicity studies were performed. The components of the vaccine (lipids and mRNA) are not expected to have genotoxic potential. This is acceptable to the CHMP.

Finally, the combined fertility and developmental toxicity study showed that SARS-CoV-2 neutralising antibody responses were present in maternal animals from prior to mating to the end of the study on postnatal day 21 as well as in foetuses and offspring. There were no vaccine-related effects on female fertility, gestation, or embryo-foetal or offspring development up to weaning. The CHMP noted that no data are available on vaccine placental transfer or excretion in milk.

2.4. Clinical aspects

2.4.1. Introduction

Pfizer and BioNTech have developed a vaccine that targets SARS-CoV-2, intended to prevent COVID-19, for which BioNTech initiated a FIH study in April 2020 in Germany (BNT162-01) and Pfizer initiated a Phase 1/2/3 study (C4591001) shortly afterwards in the US which expanded to include global sites upon initiation of the Phase 2/3 part of the study.

Phase 1/2 Study BNT162-01

Study BNT162-01 is the ongoing, FIH, Phase 1 dose level-finding study, in which healthy adults 18 to 55 years of age all receive active vaccine. This study is evaluating the safety and immunogenicity of several different candidate vaccines at various dose levels. The protocol was later amended to allow inclusion of older adult participants up to 85 years of age. The available Phase 1 safety and immunogenicity data for adults 18 to 55 years of age are reported in this application. Multiple vaccine candidates are being evaluated in this study. For each vaccine candidate, participants received escalating dose levels (N=12 per dose level) with progression to subsequent dose levels based on recommendation from a Sponsor Safety Review Committee (SRC).

Phase 1/2/3 Study C4591001

Study C4591001 is the ongoing, randomized, placebo-controlled, Phase 1/2/3 pivotal study for registration. It was started as a Phase 1/2 study in adults in the US, was then amended to expand the study to a global Phase 2/3 study planning to enrol ~44,000 participants to accrue sufficient COVID-19 cases to conduct a timely efficacy assessment; amended to include older adolescents 16 to 17 years of age, then later amended to include younger adolescents 12 to 15 years of age. In Phase 1, two age groups were studied separately, younger participants (18 to 55 years of age) and older participants (65 to 85 years of age). The study population includes male and female participants deemed healthy as determined by medical history, physical examination (if required), and clinical judgment of the investigator to be eligible for inclusion in the study. Exclusions included screened individuals with high risk of exposure to SARS-CoV-2 infection due to exposure in the workplace and/or medical conditions that represent risk factors, clinically important prior illness or laboratory abnormalities, serological evidence of prior SARS-CoV-2 infection or current SARS-CoV-2 infection as measured by polymerase chain reaction (PCR).

GCP

The Applicant claimed that the Clinical trials included in the application were performed in accordance with GCP.

The applicant has provided a statement to the effect that clinical trials conducted outside the Community were carried out in accordance with the ethical standards of Directive 2001/20/EC.

In addition, to seek further reassurance of the GCP compliance of the studies included in this dossier, in the context of the COVID-19 pandemic, EMA gathered additional information as indicated below from EU and non-EU regulatory authorities, and shared them with the CHMP to be considered in the assessment:

- a full inspection report from GCP inspection by Regierungspräsidium Karlsruhe and Paul-Ehrlich-Institut conducted at one of the investigator sites and at a CRO in Germany for the study BNT 162-01;
- Establishment Inspection Reports from GCP inspection by Food and Drug Administrations (USA Regulatory Authority) of six investigator sites in USA for study C4591001 (BNT 162-02);
- A full inspection Report and the summaries of the outcome from two GCP inspections by the National Administration of Drugs, Foods and Medical Devices (Argentinian Regulatory Authority) conducted at the single site located in Argentina for the study C4591001(BNT 162-02).

Based on the review of clinical data and the above-mentioned reports, CHMP did not identify the need for a GCP inspection of the clinical trials included in this dossier.

- Tabular overview of clinical studies

Table 1 Overview of the Clinical Development

Sponsor	Study Number (Status)	Phase Study Design	Test Product (Dose)	Number of Subjects	Type of Subjects (Age)
BioNTech	BNT162-01 (ongoing)	Phase 1/2 randomized, open-label, dose-escalation, first-in-human	BNT162b2 (1, 3, 10, 20, 30 µg)	Phase 1: 60	Adults (18-55 years of age)
BioNTech (Pfizer)	C4591001 (ongoing)	Phase 1/2/3 randomized, observer-blind, placebo-control	Phase 1: BNT162b2 (10, 20, 30 µg) Placebo	Phase 1: 90 randomized 4:1 (within each dose/age group)	Phase 1: Adults (18-55 years of age, 65-85 years of age)
			Phase 2: BNT162b2 (30 µg) Placebo	Phase 2: 360 randomized 1:1	Phase 2: Adults (18-55 years of age, 65-85 years of age)
			Phase 3: BNT162b2 (30 µg) Placebo	Phase 3: ~44,000 randomized 1:1 (includes 360 in Phase 2)	Phase 3: Adolescents, Adults (12-15 years of age, 16-55 years of age, >55 years of age)

Note: study information relevant to the scope of data presented in this application are summarized in this table.

Table 2 Overview of the pivotal phase 3 study

Study ID	No. of study centres / locations	Design	Study Posology	Study Objective	Diagnosis Incl. criteria	Primary Endpoint
C4591001	131 United States 9 Turkey 6 Germany 4 South Africa 2 Brazil 1 Argentina.	randomized, multinational, placebo-controlled, observer-blind,	2 doses of 30 µg given 21 days apart	Primary: To evaluate the efficacy of BNT162b2 against confirmed severe COVID-19 occurring from 7 and 14 days after the 2nd dose in participants with and without evidence of infection before vaccination	Healthy volunteers at risk of COVID-19	COVID-19 incidence per 1000 person-years of follow-up based on central laboratory or locally confirmed NAAT in participants with no serological or virological evidence (up to 7 days after receipt of the second dose) of past SARS-CoV-2 infection

2.4.2. Pharmacokinetics

Not applicable.

2.4.3. Pharmacodynamics

Mechanism of action

The nucleoside-modified messenger RNA in the vaccine is formulated in lipid nanoparticles, which enable delivery of the RNA into host cells to allow expression of the SARS-CoV-2 S antigen. The vaccine elicits both neutralizing antibody and cellular immune responses to the spike (S) antigen, which may contribute to protection against COVID-19.

Immunogenicity studies

For vaccines, pharmacodynamics relates to investigation of immunogenicity. The available data were generated from the phase 1/2 study BNT162-01 conducted in Germany, and from the phase 1 and 2 parts of the phase 1/2/3 study C4591001, conducted in the USA (later phases were multinational). Both studies were designed to choose the optimal vaccine candidate and an appropriate dose and schedule for further studies. Among the four prophylactic SARS-CoV-2 RNA vaccines initially tested the following two candidates were selected for further development:

BNT162b1: RNA-lipid nanoparticle (LNP) vaccine containing nucleoside-modified messenger ribonucleic acid (modRNA) that encodes the RBD (receptor-binding domain)

BNT162b2: RNA-LNP vaccine containing modRNA that encodes SARS-CoV-2 full-length, P2 mutant (see section 2.2.2), prefusion spike glycoprotein (P2 S).

Key features of the two studies are summarised in the below table.

Study Id	BNT162-01	C4591001
Title	A multi-site, Phase 1/2, 2-part, dose-escalation trial investigating the safety and immunogenicity of four prophylactic SARS-CoV-2 RNA vaccines against COVID-19 using	A Phase 1/2/3, Placebo-Controlled, Randomized, Observer-Blind, Dose-Finding Study to Evaluate the Safety, Tolerability, Immunogenicity, and Efficacy of SARS-COV-2 RNA Vaccine

	different dosing regimens in healthy adults	Candidates Against COVID-19 in Healthy Individuals
Design	This is an open-label, multi-site, Phase 1/2, 2-part, dose-escalation study. Part A of the study includes the first in human dose and dose ranging groups in healthy adults (aged 18 to 85yrs).	This is a Phase 1/2/3, randomized, multinational, placebo-controlled, observer-blind, dose-finding, vaccine candidate-selection, and efficacy study in healthy individuals. The study consists of 2 parts: Phase 1 to identify preferred vaccine candidate(s) and dose level(s); and Phase 2/3 as an expanded cohort and efficacy part.
Immunogenicity objectives	To describe the immune response in healthy adults after dose 1 only or after both dose 1 and dose 2 measured by a functional antibody titre	To describe the immune responses elicited by prophylactic BNT162 vaccines in healthy adults after 1 or 2 doses
Study population	Healthy adults aged 18 to 55yrs BNT162b1: N=84 (12/group) BNT162b2: N=60 (12/group) Healthy adults aged 56-85 yrs BNT162b1: N=36 (12/group) BNT162b2: N=36 (12/group)	Male or female participants between the ages of 18 and 55 years, inclusive, and 65 and 85 years, inclusive Phase 1 comprised 15 participants (randomization ratio of 4:1 so that 12 received active vaccine and 3 received placebo) per group; 13 vaccine groups were studied, corresponding to a total of 195 participants (the 100 µg dose was only used in the younger adult cohort)
IMP and dose level	BNT162b1: 1µg, 3µg, 10µg, 20µg, 30µg, 50µg, and 60µg. BNT162b2: 1µg, 3µg, 10µg, 20µg, 30µg	BNT162b1: 10 µg, 20 µg, 30µg, 100 µg BNT162b2: 10µg, 20µg, 30µg Placebo: normal saline
Dosing frequency	Two injections ~21d apart	Two injections ~21d apart
Immunogenicity endpoints	Virus neutralization test (VNT). Antibody binding assay, CMI assays, e.g. ELISpot and intracellular cytokine staining (ICS).	SARS-CoV-2 neutralization assay S1-binding IgG level assay RBD-binding IgG level assay N- binding antibody assay

Endpoints and Assays used to evaluate immunogenicity

In Study BNT162-01, immunogenicity was evaluated in Phase 1 using a SARS-CoV-2 serum neutralization assay to determine neutralizing titres and the fold rise in SARS-CoV-2 serum neutralizing titres. Immunogenicity was assessed at Day 1 (before Dose 1) and 7 days after Dose 1 (Day 8); and at Day 22 (before Dose 2) and 7 days, 14 days, and 21 days after Dose 2. Only qualified assays were used. In addition, T cells isolated from peripheral blood mononuclear cells (PBMCs) obtained from

whole blood samples of vaccinated Phase 1 participants were evaluated by enzyme-linked immunospot (ELISPOT) and intracellular cytokine staining visualized with fluorescence activated cell sorting (FACS). Blood samples were collected from study participants prior to the first vaccine dose and on Day 29 (7 days) after the second vaccine dose. Assessments included cytokines associated with Th1 responses such as IFNγ and IL-2 and those associated with Th2 responses such as IL-4, to analyse the induction of balanced versus Th1-dominant or Th2-dominant immune responses.

In Study C4591001, immunogenicity was evaluated in Phase 1 and Phase 2 using a SARS-CoV-2 serum neutralization assay to determine titres and a SARS-CoV-2 RBD- or S1-binding IgG direct Luminex immunoassay to determine antibody binding levels. Fold rises were assessed also. Only qualified assays were used. In Phase 1, immunogenicity was assessed at Day 1 (before Dose 1) and 7 days after Dose 1; and at Day 21 (before Dose 2) and 7 days, 14 days, and 1 month after Dose 2. Data were summarized for each dose level and age group. In Phase 2, immunogenicity was assessed at Day 1 (before Dose 1) and 1 month after Dose 2. Data were summarized for each age strata group and by evidence of prior SARS-CoV-2 infection at baseline per NAAT (PCR) or N-binding IgG assay. To facilitate interpretation of immunogenicity data generated in Study C4591001, a human convalescent serum (HCS) panel was obtained from Sanguine Biosciences (Sherman Oaks, CA), MT Group (Van Nuys, CA), and Pfizer Occupational Health and Wellness (Pearl River, NY). The 38 sera in the panel were collected from SARS-CoV-2 infected or COVID-19 diagnosed individuals 18 to 83 years of age ≥14 days after PCR-confirmed diagnosis at a time when they were asymptomatic. The serum donors had predominantly had symptomatic infections (35 of 38) including 1 who had been hospitalized. In Phase 3, exploratory immunogenicity assessments are planned at time points up to 24 months, to be reported at a later time.

These are the immunogenicity assays that were used in clinical trials:

Single-plex Direct Luminex Assay for Quantitation of SARS-CoV-2 S1-binding IgG in Human Serum

Single-plex Direct Luminex Assay for Quantitation of SARS-CoV-2 RBD-binding IgG in Human Serum

Roche Elecsys SARS-CoV-2 N Binding Antibody Assay

mNeonGreen SARS-CoV-2 Microneutralization Assay

ELISpot Assay

Intracellular Cytokine Staining (ICS) for BNT162b1 and BNT162b2

The SARS-CoV-2 Wuhan-Hu-1 isolate spike glycoprotein (GenBank accession # QHD43416.1) is the reference sequence for the recombinant S1 and RBD proteins used in the Luminex assays. The SARS-CoV-2 neutralisation assay used a previously described strain of SARS-CoV-2 (USA_WA1/2020).

Study BNT162-01

Immunogenicity - functional antibody responses (secondary objectives)

Functional antibody titre data are available up until Day 43 for younger adults (18 to 55 yrs) dosed with 1, 10, 30, 50, and 60 µg BNT162b1 on Days 1 (all dose levels) and 22 (all dose levels except 60 µg) (n=12 per group). Data are available for the 10 and 30 µg up until Day 50 for younger adults dosed with 1, 10, 20, and 30 µg BNT162b2 on Days 1 and 22 (dose level 1 µg, n=9; dose levels 10, 20, and 30 µg, n=12).

Virus neutralizing antibody GMTs for participants aged 18 to 55 years after dosing with BNT162b1, are shown in Figure 3. On Day 22, at 21 d after the first dose, virus neutralizing antibody GMTs had increased in a dose-dependent manner for all dose groups. At 7 d after the second dose (Day 29), neutralizing GMTs showed a strong, dose level dependent booster response. In the 60 µg dose group,

which was only dosed once, neutralizing GMTs remained at a lower level, indicating that a booster dose is necessary to increase functional antibody titres.

On Day 43 (21 d after the second dose of BNT162b1), neutralizing GMTs decreased (with exception of the 1 µg dose level). Day 43 virus neutralizing GMTs were 0.7-fold (1 µg) to 3.6-fold (50 µg) those of a COVID-19 HCS panel.

The COVID-19 HCS panel is comprised of 38 human COVID-19 HCS sera drawn from individuals aged 18 to 83 yrs at least 14 d after confirmed diagnosis and at a time when the individuals were asymptomatic.

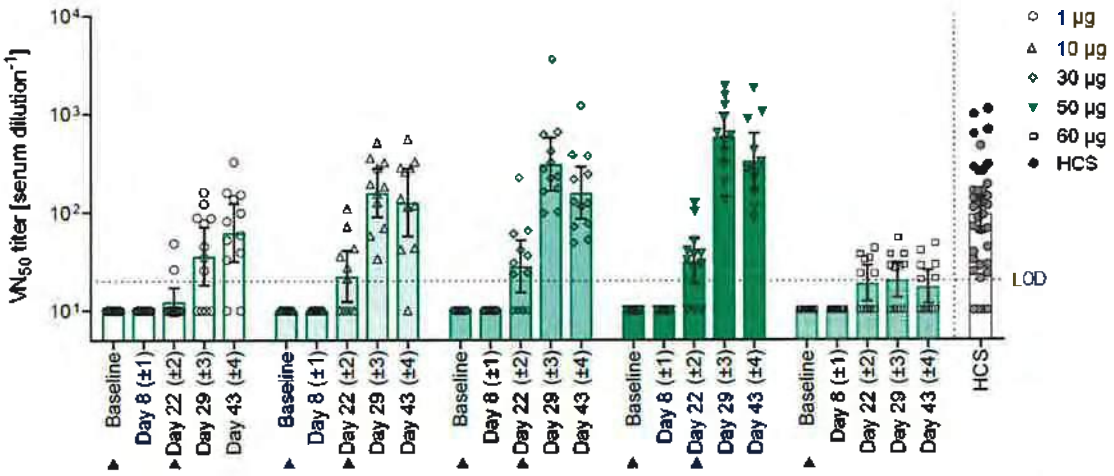


Figure 3: BNT162b1 – Functional 50% SARS-CoV-2 neutralizing antibody titers (VN50) – IMM

VN_{50} titers with 95% confidence intervals are shown for younger participants (aged 18 to 55 years) immunized with 1, 10, 30, 50, or 60 µg BNT162b1. Values smaller than the limit of detection (LOD) are plotted as 0.5*LOD. Arrowheads indicate baseline (pre-Dose 1, Day 1) and Dose 2 (Day 22). Dose 2 was not performed in the 60 µg dose group. The dotted horizontal line represents the LOD. IMM = Immunogenicity set; VN50 = 50% SARS-CoV-2 neutralizing antibody titers; HCS = human COVID-19 convalescent serum

For virus neutralizing antibody GMTs for participants aged 18 to 55 yrs after dosing with BNT162b2, see Figure 4. Participants dosed with BNT162b2 showed a strong IMP-induced antibody response. Virus neutralizing GMTs were detected at 21 d after Dose 1 (Day 22) and had increased substantially in younger participants (aged 18 to 55 yrs) immunized with ≥3 µg BNT162b2, and older participants (aged 56 to 85 yrs) immunized with 20 µg BNT162b2 by 7 d after Dose 2 (Day 29). Day 29 virus neutralizing GMTs were comparable between the younger and older adult in the 20 µg dose level cohorts. The lowest tested dose of 1 µg BNT162b2 elicited only a minimal neutralizing response in participants aged 18 to 55 yrs.

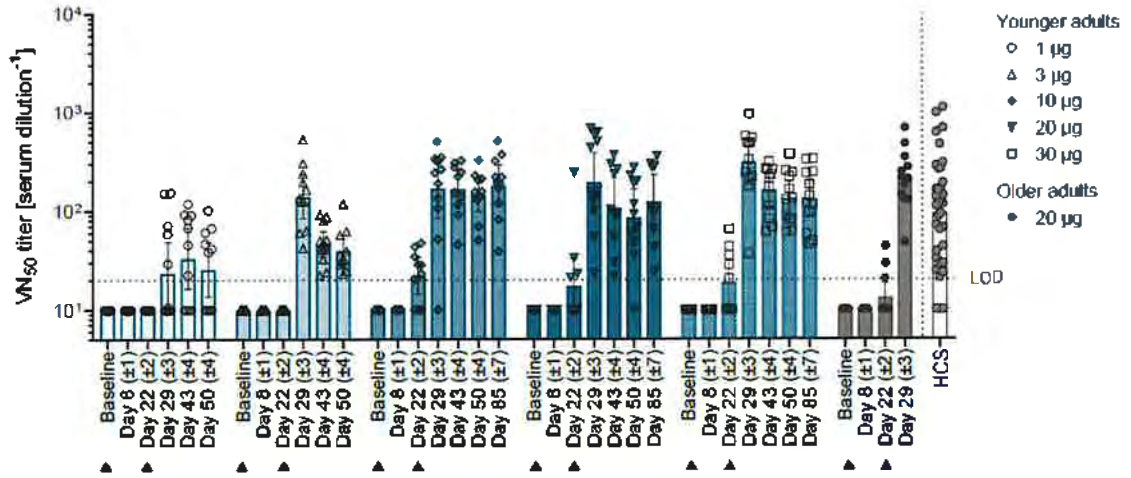

Figure 4: BNT162b2 – Functional 50% SARS-CoV-2 neutralizing antibody titres (VN50) – IMM
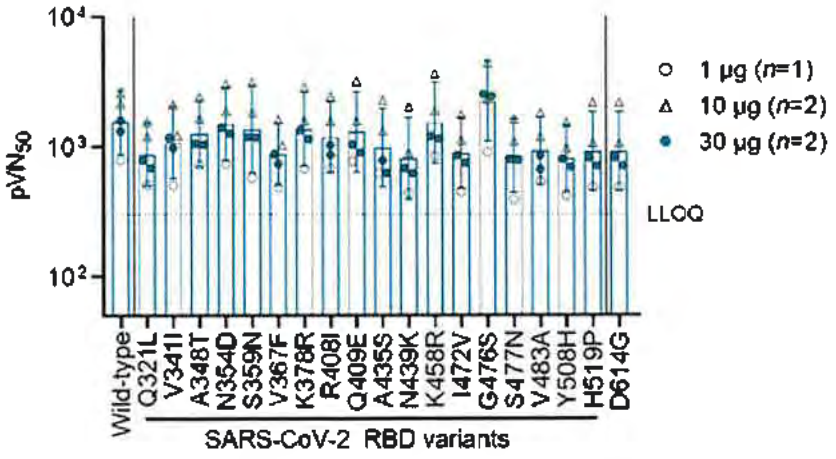
VN50 titres with 95% confidence intervals are shown for younger adults (aged 18 to 55 years) immunized with 1, 3, 10, 20, or 30 µg BNT162b2, and older adults (aged 56 to 85 yrs) immunized with 20 µg BNT162b2. Values smaller than the limit of detection (LOD) are plotted as 0.5*LOD. Arrowheads indicate baseline (pre-Dose 1, Day 1) and Dose 2 (Day 22). The dotted horizontal line represents the LOD.
IMM = Immunogenicity set; VN50 = 50% SARS-CoV-2 neutralizing antibody titers; HCS = human COVID-19 convalescent serum.

Neutralisation of different spike protein mutants

Different pseudoviruses including RBD sequence variants have been tested in a pseudovirus neutralization assay with sera from BNT162b1-and BNT162b2-immunized participants in the BNT162-01 study. Efficient neutralization of spike protein mutants was observed with sera from BNT162b1- and BNT162b2-immunized participants demonstrating the neutralization breadth of vaccine-elicited polyclonal antibodies.



BNT162b2-induced virus neutralization titers with pseudovirus 50% neutralization titers (pVNT50) across a pseudovirus panel with 19 SARS-CoV-2 spike protein variants including 18 RBD mutants and the dominant spike protein variant D614G. LLOQ = Lower level of quantification (at 300). Data shown as group (total n=5) GMT with 95% CI.

Cell mediated immunity (CMI)

CMI were measured in terms of IFNγ- producing CD4+ and CD8+ T cells by ELISpot. Both vaccine candidates elicited clear responses (baseline vs post-dose 2). Further characterisation was determined using intracellular cytokine staining for Th1 cytokines (IFNγ, IL-2) and Th2 cytokines (IL-4). Both vaccine candidates stimulated predominantly Th1 responses, both in CD4 and CD8 T cells.

Study C4591001

Methods

The statistical analyses of immunogenicity data from Study C4591001 were based on the evaluable immunogenicity populations and all-available immunogenicity populations. Phase 1 and Phase 2 data were reported as the following, for SARS-CoV-2 serum neutralizing titers and SARS-CoV-2 S1-binding and RBD-binding IgG concentrations:

- geometric mean titers/concentrations (GMTs/GMCs)
- geometric mean-fold rise (GMFR)
- geometric mean ratio (GMR) (for Phase 1 only)
- proportions of participants with ≥4-fold rise (for Phase 1 only)
- antibody titers/levels at defined thresholds (for Phase 2 only)

For immunogenicity results of SARS-CoV-2 serum neutralizing titers and S1- or RBD-binding IgG concentrations, GMTs or GMCs were computed with associated 95% CIs.

The GMFR was calculated by exponentiating the mean of the difference of logarithm transformed assay results: (later time point) – (earlier time point) with two-sided CIs. The GMR was calculated as the mean of the difference of logarithm transformed assay results: (SARS-CoV-2 serum neutralizing titers) – (SARS-CoV-2 anti-S binding antibody) for each participant, then exponentiating the mean, with two-sided CIs.

Results

The study set out to evaluate 2 SARS-CoV-2 RNA vaccine candidates, as a 2-dose (separated by 21 days) schedule, at different dose levels (BNT162b1: 10, 20, 30, and 100 µg, BNT162b2: 10, 20, and 30 µg) and in different age groups (18 55 y; 65-85 y), to select a vaccine and dose level for further testing in Phase 2/3. Cut-off date: 24-Aug-2020 (1 month post-dose 2 = D52).

Immunogenicity results are available for both adult age groups up to 1 month post-Dose 2 for the BNT162b1 and BNT162b2 vaccine candidates at the 10-µg, 20-µg, and 30-µg dose levels, and up to 7 weeks after Dose 1 of BNT162b1 at the 100-µg dose level (younger age group only).

Results for the 7 days after Dose 1 time point are only analysed and presented in the younger age group (18 to 55 years of age) for 10 µg and 30 µg BNT162b1.

Immunogenicity results SARS-CoV-2 Neutralizing Titres

BNT162b1

In the younger age group, SARS-CoV-2 50% neutralizing GMTs modestly increased by Day 21 after Dose 1 and were substantially increased 7 days after Dose 2 (Day 28) of BNT162b1 (Figure 5).

Generally similar trends were observed in the older age group, with higher GMTs observed in the 20-µg and 30-µg dose groups of BNT162b1 compared to the 10-µg dose group (Figure 6). In the older age

group, the SARS-CoV-2 50% neutralizing GMTs were generally lower than the GMTs in the younger age group.

BNT162b2

In the younger age group, SARS-CoV-2 50% neutralizing GMTs increased by Day 21 after Dose 1 and were substantially increased 7 days after Dose 2 (Day 28) of BNT162b2 (Figure 7).

Similar trends were generally observed in the older age group, with higher GMTs observed in the 30-µg dose groups compared to the 20-µg and 10-µg dose groups (Figure 8). In the older age group, SARS-CoV-2 50% neutralizing GMTs were generally lower than the GMTs in the younger age group.

2.4.4. Discussion on clinical pharmacology

The choice and dose of vaccine candidate was based on the results of two clinical phase I studies. Immune responses and safety of the two candidates were studied in both studies. The immune responses in terms of neutralising antibody responses clearly demonstrated that two doses resulted in increased geometric mean titres (GMTs) compared to responses after only the first dose. Thus, in the absence of a serological correlate of protection, these data supported that two doses would be needed in adults. The responses were numerically higher in higher dose groups compared to lower doses but did not substantially differ between 10ug and 30ug. The neutralising antibody responses between the two vaccine candidates are considered similar although no formal comparison was made. The responses to the vaccines were higher compared to a pool of human convalescent sera in study BNT162-001. In both studies subjects 55 years of age and older were included as well as younger adults. The responses in elderly were lower compared to younger adults, but the difference is likely of no clinical relevance, also considering the delayed peak.

For BNT162b1 and BNT162b2, the S1- and RBD-binding IgG kinetics were comparable to the kinetics of neutralizing antibodies, with lower IgG concentrations in older age group than in younger age group.

Further evaluation of antibody persistence is ongoing. Neutralizing antibody titres will be followed until the end of 162 days post-dose 2 for study BNT162-01 and up to 2-years for study C459001. Final study report from study C4591001 is requested to be submitted as soon as available (specific obligation).

Immune responses induced by the vaccine against emerging circulating strains of SARS-CoV-2 will be also be investigated. Effectiveness studies included in the RMP will be important to understand the performance of the vaccine in case of e.g. mutating variants.

Efficient neutralization of spike protein mutants including RBD sequence variants was observed with sera from vaccine-immunized study BNT162-01 participants, demonstrating the neutralization breadth of vaccine-elicited polyclonal antibodies. This may be important to consider when facing emerging variants with mutations in the spike proteins, e.g. the UK variant, as the vaccine might still be able to confer sufficient cross-neutralisation.

Further characterisation of immune responses was included in study BNT162-001. Cellular immune responses were demonstrated in terms of IFNγ-producing CD4 and CD8 T cells. In addition, a clear Th1-polarised response, i.e. IFNγ/IL-2 ICS and limited IL-4 ICS was shown, which is reassuring in terms of lack of VAED. For the 30 µg dose cohort vaccinated with BNT162b2, CD4 and CD8 cytokine responses showed the same intensity in adults and older adults, whereas for the 30 µg dose cohort vaccinated with BNT162b1, RBD-specific IL-2 producing CD4+ and CD8+ T cells were reduced in older adults.

2.4.5. Conclusions on clinical pharmacology

The immune response data overall support the choice of vaccine candidate, BNT162b2, and the choice of a 2-dose schedule of 30 µg. Final study report from study C4591001 is requested to be submitted as soon as available (specific obligation), including data on persistence of immune responses.

2.5. Clinical efficacy

2.5.1. Dose response study

See section 2.4.3.

2.5.2. Main study

Title of study

Study C4951001: A Phase 1/2/3, Placebo-Controlled, Randomized, Observer-Blind, Dose-Finding Study to Evaluate the Safety, Tolerability, Immunogenicity, and Efficacy of SARS-COV-2 RNA Vaccine Candidates Against COVID-19 in Healthy Individuals

Methods

Study Participants

Main Inclusion criteria:

- Male or female participants between the ages of 18 and 55 years, inclusive, and 65 and 85 years, inclusive (Phase 1), or ≥12 years (Phase 2/3) at randomization.
- Healthy participants with pre-existing stable disease, defined as disease not requiring significant change in therapy or hospitalization for worsening disease during the 6 weeks

before enrolment, could be included. Potential participants with chronic stable HIV, HCV, or HBV infection may be considered for inclusion if they fulfil the criteria specified in the protocol.

- Phase 2/3 only: Participants who, in the judgment of the investigator, were at higher risk for acquiring COVID-19 (including, but not limited to, use of mass transportation, relevant demographics, and frontline essential workers).
- Capable of giving personal signed informed consent/have parent(s)/legal guardian capable of giving signed informed consent

Exclusion criteria:

- Other medical or psychiatric condition including recent or active suicidal ideation/behaviour or laboratory abnormality that increased the risk of study participation or, in the investigator's judgment, made the participant inappropriate for the study.
- History of severe adverse reaction associated with a vaccine and/or severe allergic reaction to any component of the study intervention.
- Receipt of medications intended to prevent COVID-19.
- Previous clinical or microbiological diagnosis of COVID-19.
- Immunocompromised individuals with known or suspected immunodeficiency, as determined by history and/or laboratory/physical examination.
- Bleeding diathesis or condition associated with prolonged bleeding that would, in the opinion of the investigator, contraindicate intramuscular injection.
- Women who are pregnant or breastfeeding.
- Previous vaccination with any coronavirus vaccine.
- Individuals who received treatment with immunosuppressive therapy, including cytotoxic agents or systemic corticosteroids, e.g., for cancer or an autoimmune disease, or planned receipt throughout the study. If systemic corticosteroids were administered short term (<14 days) for treatment of an acute illness, participants should not have been enrolled into the study until corticosteroid therapy had been discontinued for at least 28 days before study intervention administration. Inhaled/nebulized, intra-articular, intrabursal, or topical (skin or eyes) corticosteroids were permitted.
- Receipt of blood/plasma products or immunoglobulin, from 60 days before study intervention administration or planned receipt throughout the study.
- Participation in other studies involving study intervention within 28 days prior to study entry and/or during study participation
- Previous participation in other studies involving study intervention containing lipid nanoparticles.

Treatments

The vaccine candidate selected for Phase 2/3 evaluation was BNT162b2 at a dose of 30 µg. In phase 2/3 the participants were randomized 1:1 to receive vaccine or placebo, normal saline (0.9% sodium chloride solution for injection). The injection was intramuscular for both vaccine and the placebo.

Available safety, efficacy and immunogenicity data pertain to vaccine made according with the manufacturing process employed for clinical trial batches.

The scale of the BNT162b2 manufacturing has been increased to support future supply. BNT162b2 generated using the manufacturing process supporting an increased supply (commercial process) will be administered to approximately 250 participants 16 to 55 years of age, per lot, in the study. Data are expected in February 2021. See the Quality section regarding comparability of clinical lots and commercial lots.

Objectives

The outcomes of the primary efficacy objectives were included in the Clinical Study Report submitted in this application. Results of the secondary objectives are expected during 2021.

Primary efficacy objectives

- To evaluate the efficacy of prophylactic BNT162b2 against confirmed COVID-19 occurring from 7 days after the second dose in participants without evidence of infection before vaccination
- To evaluate the efficacy of prophylactic BNT162b2 against confirmed COVID-19 occurring from 7 days after the second dose in participants with and without evidence of infection before vaccination

Primary safety objectives

- To define the safety profile of prophylactic BNT162b2 in the first 360 participants randomized (Phase 2)
- To define the safety profile of prophylactic BNT162b2 in all participants randomized in Phase 2/3
- To define the safety profile of prophylactic BNT162b2 in participants 12 to 15 years of age in Phase 3

Secondary efficacy objectives

- To evaluate the efficacy of prophylactic BNT162b2 against confirmed COVID-19 occurring from 14 days after the second dose in participants without evidence of infection before vaccination
- To evaluate the efficacy of prophylactic BNT162b2 against confirmed COVID-19 occurring from 14 days after the second dose in participants with and without evidence of infection before vaccination
- To evaluate the efficacy of prophylactic BNT162b2 against confirmed severe COVID-19 occurring from 7 days and from 14 days after the second dose in participants without evidence of infection before vaccination
- To evaluate the efficacy of prophylactic BNT162b2 against confirmed severe COVID-19 occurring from 7 days and from 14 days after the second dose in participants with and without evidence of infection before vaccination
- To describe the efficacy of prophylactic BNT162b2 against confirmed COVID-19 (according to the CDC-defined symptoms) occurring from 7 days and from 14 days after the second dose in participants without evidence of infection before vaccination

- To describe the efficacy of prophylactic BNT162b2 against confirmed COVID-19 (according to the CDC-defined symptoms) occurring from 7 days and from 14 days after the second dose in participants with and without evidence of infection before vaccination.

Secondary immunogenicity objectives

- To demonstrate the noninferiority of the immune response to prophylactic BNT162b2 in participants 12 to 15 years of age compared to participants 16 to 25 years of age (data not included in this report)

Exploratory objectives

- To evaluate the immune response over time to prophylactic BNT162b2 and persistence of immune response in participants with and without serological or virological evidence of SARS-CoV-2 infection before vaccination
- To evaluate the immune response (non-S) to SARS-CoV-2 in participants with and without confirmed COVID-19 during the study
- To describe the serological responses to the BNT vaccine candidate in cases of:
  - Confirmed COVID-19
  - Confirmed severe COVID-19
  - SARS-CoV-2 infection without confirmed COVID-19
- To describe the safety, immunogenicity, and efficacy of prophylactic BNT162b2 in individuals with confirmed stable HIV disease
- To describe the safety and immunogenicity of prophylactic BNT162b2 in individuals 16 to 55 years of age vaccinated with study intervention produced by two different manufacturing processes (see under Treatment).

Outcomes/endpoints

Immunogenicity

See pharmacodynamics section for description of immunological methods used in phase 1 and 2 of this study. The same methods are used also in phase 3, but results are not yet available.

Primary Efficacy Endpoints

First primary endpoint: COVID-19 incidence per 1000 person-years of follow-up in participants without serological or virological evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2.

Second primary endpoint: COVID-19 incidence per 1000 person-years of follow-up in participants with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2.

Secondary Efficacy Endpoints

COVID-19 confirmed at least 14 days after Dose 2: COVID-19 incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without serological or virological evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥14 days after Dose 2.

Severe COVID-19: incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed either (1) ≥7 days after Dose 2 or (2) ≥14 days after Dose 2.

COVID-19 Case Definitions

Participants who developed any potential COVID-19 symptoms were to contact the site immediately and, if confirmed, to participate in an in-person or telehealth visit as soon as possible (within 3 days of symptom onset and at the latest 4 days after symptom resolution). At the visit (or prior to the visit, if a self-swab was used), investigators were to collect clinical information and results from local standard-of-care tests sufficient to confirm a COVID-19 diagnosis. Investigators were to obtain a nasal swab (mid-turbinate) for testing at a central laboratory using a validated reverse transcription–polymerase chain reaction (RT-PCR) test (Cepheid; FDA approved under EUA) to detect SARS-CoV-2. If the evaluation was conducted by telehealth, the participant was to self-collect a nasal swab and ship for assessment at the central laboratory. A local nucleic acid amplification test (NAAT) result was only acceptable if it met protocol specified criteria and if a central laboratory result was not available.

Two definitions of SARS-CoV-2 related cases, and SARS-CoV-2 related severe cases, will be considered (for both, the onset date of the case will be the date that symptoms were first experienced by the participant; if new symptoms are reported within 4 days after resolution of all previous symptoms, they will be considered as part of a single illness):

Confirmed COVID-19 (defined for FDA guidance): presence of at least 1 of the following symptoms and SARS-CoV-2 NAAT-positive during, or within 4 days before or after, the symptomatic period, either at the central laboratory or at a local testing facility (using an acceptable test):

- Fever;
- New or increased cough;
- New or increased shortness of breath;
- Chills;
- New or increased muscle pain;
- New loss of taste or smell;
- Sore throat;
- Diarrhoea;
- Vomiting.

The second definition, which may be updated as more is learned about COVID-19, will include the following additional symptoms defined by the CDC:

- Fatigue;
- Headache;
- Nasal congestion or runny nose;
- Nausea.

Confirmed severe COVID-19: confirmed COVID-19 and presence of at least 1 of the following:

- Clinical signs at rest indicative of severe systemic illness (RR ≥30 breaths per minute, HR ≥125 beats per minute, SpO2 ≤93% on room air at sea level, or PaO2/FiO2<300mm Hg);

- Respiratory failure (defined as needing high-flow oxygen, non-invasive ventilation, mechanical ventilation, or ECMO);
- Evidence of shock (SBP <90 mm Hg, DBP <60 mm Hg, or requiring vasopressors);
- Significant acute renal, hepatic, or neurologic dysfunction;
- Admission to an ICU;
- Death.

In addition, evidence of prior infection was determined by virological testing via NAAT on mid-turbinate swab and serological testing for IgG to the SARS-CoV-2 N-antigen. A serological definition will be used for participants without clinical presentation of COVID-19:

- Confirmed seroconversion to SARS-CoV-2 without confirmed COVID-19: positive N-binding antibody result in a participant with a prior negative N-binding antibody result.

In addition, prior infection with SARS-CoV-2 was assessed also at Dose 2 (NAAT) and is being evaluated for up to 24 months. The purpose is to assess persistence of efficacy, explore efficacy against asymptomatic SARS-CoV-2 infections, and ensure safety in both seronegative and seropositive participants.

Sample size

For Phase 2/3, with assumptions of a true VE of 60% after the second dose of investigational product, a total of approximately 164 first confirmed COVID-19 illness cases will provide 90% power to conclude true VE >30% with high probability, allowing early stopping for efficacy at the IA. This would be achieved with 17,600 evaluable participants per group or 21,999 vaccine recipients randomized in a 1:1 ratio with placebo, for a total sample size of 43,998, based on the assumption of a 1.3% illness rate per year in the placebo group, accrual of 164 first primary-endpoint cases within 6 months, and 20% of the participants being non-evaluable or having serological evidence of prior infection with SARS-CoV-2, potentially making them immune to further infection. Dependent upon the evolution of the pandemic, it is possible that the COVID-19 attack rate may be much higher, in which case accrual would be expected to be more rapid, enabling the study's primary endpoint to be evaluated much sooner.

Randomisation and Blinding (masking)

Allocation of participants to vaccine groups were performed through the use of an IRT system (IWR). Participants were randomised 1:1 to active vaccine or placebo.

The trial included participants ≥12 years of age, stratified as follows: 12 to 15, 16 to 55 years or >56 years. It was intended that a minimum of 40% of participants were to be enrolled in the >56-year stratum.

The study staff receiving, storing, dispensing, preparing, and administering the study interventions were unblinded. All other study and site personnel, including the investigator, investigator staff, and participants, were blinded to study intervention assignments.

Exceptions to blinding for e.g. DMC activities were described and found acceptable.

Efficacy Analysis Methods

During Phase 2/3, interim analyses were pre-specified in the protocol to be conducted after accrual of at least 62, 92, and 120 evaluable COVID-19 cases, where overwhelming efficacy could be declared if the primary endpoint was met with a posterior probability that the true VE is >30% (i.e., Pr[VE >30%|data] >99.5% at an interim analysis or >98.6% at the final analysis). The success threshold for each interim analysis was calibrated to protect overall type I error at 2.5%. Futility was also assessed, and the study could be stopped for lack of benefit if the predicted probability of demonstrating vaccine efficacy at the final analysis was <5% at any of the first 2 planned interim analyses. Efficacy and futility boundaries were applied in a nonbinding way. The calculation of posterior probability and the credible interval were adjusted for surveillance time. For subgroup analyses of the primary efficacy endpoint, a 2-sided 95% confidence interval (CI) was calculated. VE is defined as 100% × (1 – IRR), where illness rate ratio (IRR) is calculated as the ratio of first confirmed COVID-19 illness rate in the vaccine group to the corresponding illness rate in the placebo group. VE is demonstrated if there is convincing evidence (i.e., posterior probability greater than 99.5% at an interim analysis or greater than 98.6% at the final analysis) that the true VE of BNT162b2 is >30% using a beta-binomial model, where VE represents efficacy for prophylactic BNT162b2 against confirmed COVID-19 in participants without evidence of prior SARS-CoV-2 infection before and during the vaccination regimen. Participants with positive or unknown NAAT results at any illness visit prior to 7 days after Dose 2 were not included in the evaluation for VE. Cases were counted from 7 days after Dose 2.

The interim analysis was performed for the first primary efficacy endpoint only. Other efficacy data analysed for the interim analysis were summarized with descriptive summary statistics, including COVID-19 case counts in the BNT162b2 and placebo groups on the basis of:

- evidence of prior SARS-CoV-2 infection at baseline per NAAT or N-antigen binding assay
- subgroup status (i.e., age, sex, race, ethnicity baseline SARS-CoV-2 status)
- COVID-19 cases meeting protocol criteria as severe after the first and second doses.

Overwhelming efficacy success criteria were met at the first interim analysis, so further formal interim analyses would not be conducted. The final analysis of all protocol specified primary and secondary efficacy endpoints was pre-specified in the protocol to be conducted after accrual of the final number of COVID-19 cases (at least 164 cases). Subgroup analyses of VE were performed for the primary endpoints and secondary endpoint of severe COVID-19 cases. Additional post hoc analyses of subgroups defined by comorbidity risk assessment were performed. Secondary efficacy was analysed in the same manner as primary efficacy (Section 2.5.4.1.2.2), using the cases definitions for severe COVID-19 and CDC criteria for COVID-19

Statistical methods

The estimands to evaluate the efficacy objectives were based on evaluable populations for efficacy. These estimands estimate the vaccine effect in the hypothetical setting where participants follow the study schedules and protocol requirements as directed. In addition, VE was also analysed by all-available efficacy population.

The evaluable efficacy population included all eligible randomized participants who received all vaccination(s) as randomized, with Dose 2 received within the predefined window (19-42 days after Dose 1),and had no other important protocol deviations as determined by the clinician on or before 7 days after Dose 2. This was the primary analysis population for all efficacy analyses. Additional analyses based on the all-available efficacy populations, including all randomized participants who completed 1 and 2 vaccination doses respectively, were also performed.

The two primary endpoints were tested hierarchically. Key secondary efficacy endpoints were evaluated sequentially in a prespecified order after the primary endpoints were met. Missing data were not imputed for the primary or secondary analyses. Sensitivity analysis of missing laboratory data was performed for the primary endpoint with MNAR assumption.

VE was estimated as follows: 100 × (1 − IRR), where IRR is the calculated ratio of confirmed COVID-19 illness per 1000 person-years follow-up in the active vaccine group to the corresponding illness rate in the placebo group from 7 days after the second dose.

A Bayesian approach was used for the primary and secondary endpoints. A beta prior, beta (0.700102, 1), was used for θ = (1-VE)/(2-VE). The prior was centred at θ = 0.4118 (VE=30%). The 95% interval for θ is (0.005, 0.964) and the corresponding prior 95% interval for VE is (-26.2, 0.995). The Bayesian approach was not used for the point estimate for VE. At final analysis, efficacy was to be declared if the posterior probability of VE greater than or equal to 30% ("p") > 98.60%.

During Phase 2/3, 4 interim analyses (IAs) were planned to be performed by an unblinded statistical team after accrual of at least 32, 62, 92, and 120 cases. The final analysis was to be performed when 164 cases were observed. However, only one interim analysis was performed, at 94 cases. The final analysis was performed with 170 cases. At the time of the IAs, futility and VE with respect to the first primary endpoint were planned to be assessed. The IA that was performed was successful, as was the final analysis, and results were consistent with the IA.

The success threshold for each interim analysis was to be calibrated to protect overall type I error at 2.5%. The risk of falsely concluding the VE to be above 30% (the type I error rate) with the proposed Bayesian model and over the interim analyses and final analysis under assumption of 30% vaccine efficacy is 0.021 (one sided). Hence the type I error rate for the primary endpoint is controlled. Although only one interim analysis was performed, the overall Type I error (overall probability of success when true VE=30%) was controlled at 0.025 with the originally proposed success/futility boundaries.

Although Bayesian analysis are not usually accepted as confirmatory evidence in pivotal trials, the magnitude of the effect in this study, makes this concern redundant. Hence, the conclusions of the inference are considered robust.

Note : 1 subject was randomised but did not sign informed consent and is not included in any analysis population
Note: because of a dosing error, 2 subjects received an additional dose of BNT162b2 (30µg) and one dose of placebo
Note: HIV-positive subjects are included in this summary but not included in the analysis of the overall study objectives.
a. N=number of randomised subjects in the specified group, or the total sample. This value is the denominator for the percentage calculations
b. n=number of subjects with the specific characteristics

Recruitment

This study is ongoing, and participants are continuing to be enrolled and evaluated in Phase 3.

Subject First Visit: 29 April 2020

Data Cut-off dates:

- 24 August 2020 (Phase 1 safety and immunogenicity data through 1 month after Dose 2)
- 02 September 2020 (Phase 2 safety data 7 days after Dose 2 only)
- 06 October 2020 (Phase 2/3 safety data 1 month after Dose 2 for the first 6610 participants, and available safety data for all 36,855 participants)
- 04 November 2020 (Phase 2/3 first interim analysis for efficacy at 94 cases)

As a result, 44,822 subjects have been enrolled and 43,386 subjects have been randomised at 153 centres, in 6 countries worldwide, including: United States (131 centres, 33,068 subjects), Argentina (1 site, 5,776 subjects), Brazil (2 sites, 2,900 subjects), Turkey (9 sites, 342 subjects), South Africa (4 sites, 800 subjects) and Germany (6 sites, 500 subjects).

Conduct of the study

This study has gone through extensive changes or amendments. The amendments of the phase 1 of the study are deemed acceptable for a dose-finding design. Protocol amendments concerning the phase 3 of the study are overall adequately motivated and acceptable, since they are not expected to affect the conclusions on efficacy. Main Amendments have allowed to include adolescents from 12 to 15 years in the study and added corresponding objectives. Furthermore, secondary efficacy endpoints to include COVID-19 cases that occurred from 14 days after the second dose were added. The SAP was amended twice in line with protocol amendments.

Baseline data

Overall, demographic characteristics were well balanced between study groups.

Demographics (population for the primary efficacy endpoint)[a]

	Comirnaty (N=18,242) n (%)	**Placebo (N=18,379) n (%)**

The study excluded participants who were immunocompromised and those who had previous clinical or microbiological diagnosis of COVID-19. Participants with pre-existing stable disease, defined as disease

not requiring significant change in therapy or hospitalization for worsening disease during the 6 weeks before enrolment, were included as were participants with known stable infection with human immunodeficiency virus (HIV), hepatitis C virus (HCV) or hepatitis B virus (HBV).

Numbers analysed

The disposition of the efficacy populations is described in the Table below. There was an imbalance between the two study groups on the number of subjects excluded from the evaluable efficacy population. The two reasons responsible for this imbalance were "Dosing/administration error, subject did not receive correct dose of vaccine" (n=105 in vaccines and n=3 in placebo) and "IP administered that was deemed not suitable for use by Almac" (n=144 in vaccines and n=0 in placebo). There may be several explanations for this imbalance as listed below:

- As the placebo was a fixed volume of saline, with no dilution required, the likelihood of a dosing error in the placebo group was lower compared to vaccine, which did required dilution.
- An isolated dosing/administrative error event in one clinical centre affecting a higher number of participants receiving BNT162b2 (n=52 participants) has contributed to this imbalance.
- Almac was responsible for determining suitability for use of investigational product that was subject to a temperature excursion. Due to the differences in the required storage conditions (ambient for the placebo versus ultracold for the BNT162b2), temperature excursions were not an issue for the placebo but were for BNT162b2.

The protocol design was such that, if a participant experienced any of the specified trigger symptoms that could indicate COVID-19, a potential COVID-19 illness visit should occur, including obtaining a swab for the central laboratory.

Table 4 Efficacy Populations

	Vaccine Group (as Randomized)		
	BNT162b2 (30 µg) n[a] (%)	Placebo n[a] (%)	Total n[a] (%)

Had other important protocol deviations on or prior to 7days after Dose 2	311 (1.4)	60 (0.3)	371 (0.8)
Had other important protocol deviations on or prior to 14 days after Dose 2	311 (1.4)	61 (0.3)	372 (0.9)

Note: HIV-positive subjects are included in this summary but not included in the analyses of the overall study objectives.
a. n = Number of subjects with the specified characteristic.
b. These values are the denominators for the percentage calculations.
c. Subjects may have been excluded for more than 1 reason.

Outcomes and estimation

Primary Efficacy Endpoints – Final Analysis

The result for the first primary efficacy analysis is shown in Table 5. VE against confirmed COVID-19 occurring at least 7 days after Dose 2 was 95.0%, with 8 COVID-19 cases in the BNT162b2 group compared to 162 COVID-19 cases in the placebo group.

The vaccine efficacy of BNT162b2 for the same primary efficacy endpoint based on the Dose 2 all-available efficacy population was 95.2%, with 8 and 165 cases in the BNT162b2 and placebo group.

Table 5 Vaccine Efficacy – First COVID-19 Occurrence From 7 Days After Dose 2 – Subjects Without Evidence of Infection Prior to 7 Days After Dose 2 – Evaluable Efficacy (7 Days) Population

	Vaccine Group (as Randomized)						
	BNT162b2 (30 µg) (N[a]=18198)		Placebo (N[a]=18325)				
Efficacy Endpoint	n1[b]	Surveillance Time[c] (n2[d])	n1[b]	Surveillance Time[c] (n2[d])	VE (%)	(95% CI[e])	Pr (VE >30% | data)[f]
First COVID-19 occurrence from 7 days after Dose 2	8	2.214 (17411)	162	2.222 (17511)	95.0	(90.3, 97.6)	>0.9999

Abbreviations: N-binding = SARS-CoV-2 nucleoprotein–binding; NAAT = nucleic acid amplification test; SARS-CoV-2 =severe acute respiratory syndrome coronavirus 2; VE = vaccine efficacy.
Note: Subjects who had no serological or virological evidence (prior to 7 days after receipt of the last dose) of past SARS-CoV-2 infection (ie, N-binding antibody [serum] negative at Visit 1 and SARS-CoV-2 not detected by NAAT [nasal swab] at Visits 1 and 2), and had negative NAAT (nasal swab) at any unscheduled visit prior to 7 days after Dose 2 were included in the analysis.
a. N = number of subjects in the specified group.
b. n1 = Number of subjects meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details.
f. Posterior probability (Pr) was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details

For the second primary efficacy endpoint, VE for BNT162b2 against confirmed COVID-19 was evaluated in participants with or without evidence of prior SARS-CoV-2 infection through 7 days after Dose 2. Cases were counted from 7 days after Dose 2 (Table 6). VE against confirmed COVID-19 occurring at least 7 days after Dose 2 was 94.6%, with 9 and 169 cases in the BNT162b2 and placebo groups respectively.

The vaccine efficacy of BNT162b2 for the same primary efficacy endpoint based on the Dose 2 all-available efficacy population was 94.8%, with and 9 and 172 cases in the BNT162b2 and placebo group, respectively.

Table 6 Vaccine Efficacy – First COVID-19 Occurrence From 7 Days After Dose 2 Subjects With or Without Evidence of Infection Prior to 7 Days After Dose 2 – Evaluable Efficacy (7 Days) Population

	Vaccine Group (as Randomized)						
	BNT162b2 (30 µg) (N[a]=19965)		Placebo (N[a]=20172)				
Efficacy Endpoint	n1[b]	Surveillance Time[c] (n2[d])	n1[b]	Surveillance Time[c] (n2[d])	VE (%)	(95% CI[e])	Pr (VE >30% | data)[f]
First COVID-19 occurrence from 7 days after Dose 2	9	2.332 (18559)	169	2.345 (18708)	94.6	(89.9, 97.3)	>0.9999

Abbreviations: VE = vaccine efficacy.
a. N = number of subjects in the specified group.
b. n1 = Number of subjects meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details.
f. Posterior probability (Pr) was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details.

However the seropositive subjects were not many: among 38,000 subjects there were 407 individuals seropositive in the vaccine group and 436 in the placebo group in the age strata 16-55 YOA, and 150 individual seropositive in the vaccine group and 152 in the placebo group in the >55 YOA age strata.

All Confirmed Cases of COVID-19 After Dose 1

An analysis of the cases occurring from dose 1 and until dose 2 or 1 week after dose 2 provides information on onset of protection.

All reports of COVID-19 with onset at any time after Dose 1 are accounted for in Table 7, which provides a summary of cases for all participants in the Dose 1 all-available efficacy (modified intention-to-treat) population, regardless of evidence of infection before or during the vaccination regimen. Among these participants, 50 cases of COVID-19 occurred after Dose 1 in the BNT162b2 group compared to 275 cases in the placebo group (Table 7). Notably, in the BNT162b2 group, most cases occurred before Dose 2.

Figure 9 displays cumulative incidence for the first COVID-19 occurrence after Dose 1 among all vaccinated participants based on Dose 1 all-available efficacy (modified intention-to-treat) population. Disease onset appears to track together for BNT162b2 and placebo until approximately 14 days after Dose 1, at which point the curves diverge, with cases steadily accumulating in the placebo group, while remaining virtually flat in the BNT162b2 group. From table 7 and figure 9 it is evident that the first dose offers partial protection, while few cases occur after the second dose.

Table 7 Vaccine Efficacy – First COVID-19 Occurrence After Dose 1 – Dose 1 All- Available Efficacy Population

	Vaccine Group (as Randomized)					
	BNT162b2 (30 µg) (N[a]=21669)		Placebo (N[a]=21686)			
Efficacy Endpoint Subgroup	n1[b]	Surveillance Time[c] (n2[d])	n1[b]	Surveillance Time[c] (n2[d])	VE (%)	(95% CI[e])
First COVID-19 occurrence after Dose 1	50	4.015 (21314)	275	3.982 (21258)	82.0	(75.6, 86.9)
After Dose 1 to before Dose 2	39		82		52.4	(29.5, 68.4)
≥10 days after Dose 1 to before Dose 2	6		45		86.7	(68.6, 95.4)
Dose 2 to 7 days after Dose 2	2		21		90.5	(61.0, 98.9)
≥7 Days after Dose 2	9		172		94.8	(89.8, 97.6)

Abbreviations: VE = vaccine efficacy.
a. N = number of subjects in the specified group.
b. n1 = Number of subjects meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from Dose 1 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. Confidence interval (CI) for VE is derived based on the Clopper and Pearson method (adjusted for surveillance time for overall row).

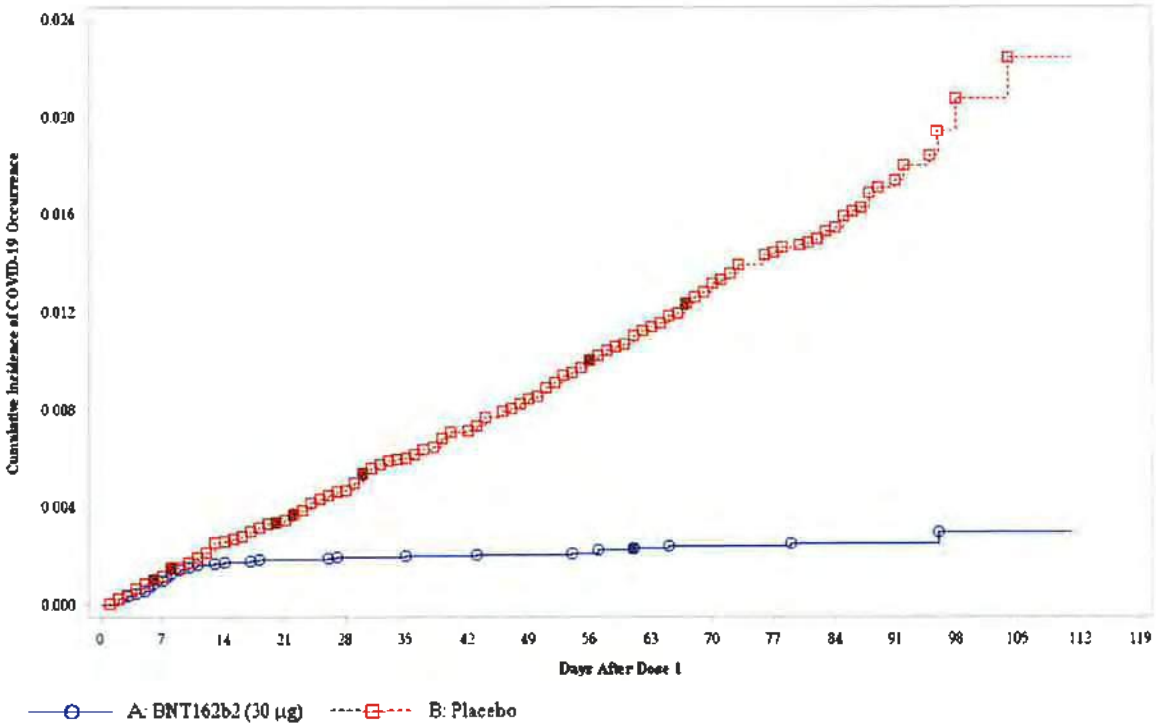

Figure 9. Cumulative Incidence Curves for the First COVID-19 Occurrence After Dose 1 – Dose 1 All-Available Efficacy Population

Immunogenicity results

The immunogenicity part of study C4591001 are presented in this section and aimed to confirm the conclusions on safety and immunogenicity from phase 1. These are the only immunogenicity results from a larger study population available at this stage, and further results from phase 3 are expected post approval. In addition, any data generated in attempts to establish a serological correlate of protection are expected to be reported when available.

The results of the immunogenicity analyses here reported are generated from the Dose 2 evaluable immunogenicity population; baseline positive participants (by N-binding antibody or positive NAAT at Visit 1) were not excluded from these analyses.

SARS-CoV-2 Neutralizing Titres and S1-Binding IgG Concentrations GMTs/GMCs

At 1 month after Dose 2 (Day 52) of BNT162b2, there were substantial increases in SARS-CoV-2 50% neutralizing GMTs (Figure 10) and S1-binding IgG concentrations (GMCs) (Figure 11). GMTs/GMCs were higher in younger participants (18 to 55 years of age) than in older participants (56 to 85 years of age). Similar trends were observed for the SARS-CoV-2 90% neutralizing GMTs (data not shown in this report).

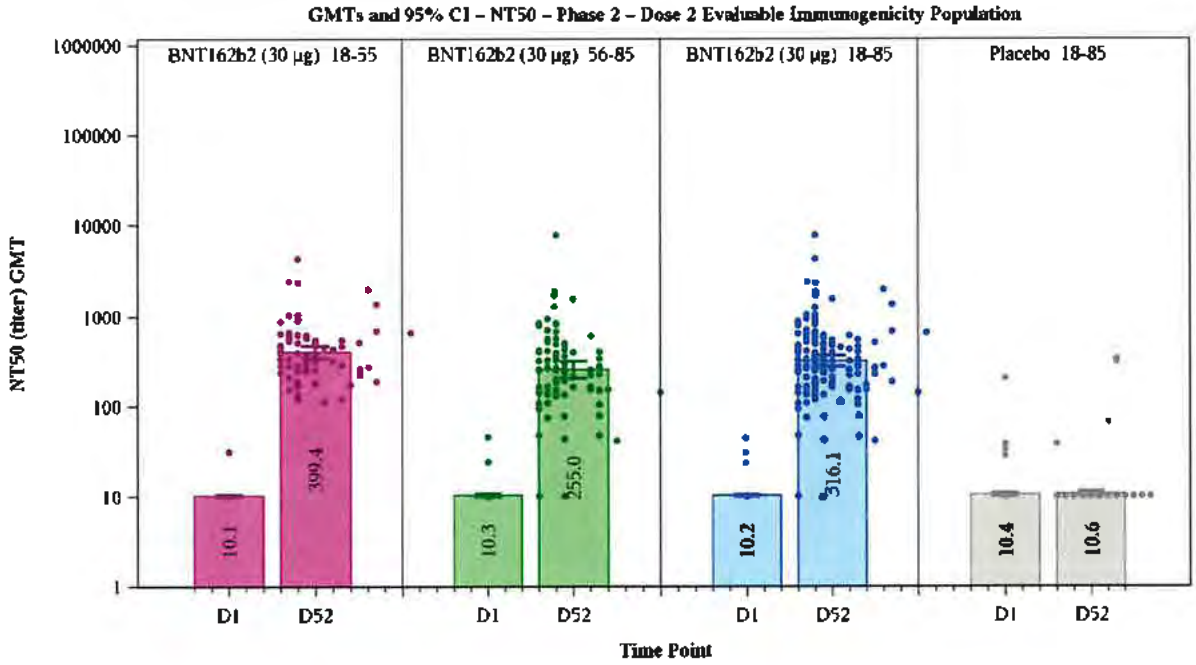

Figure 10. Geometric Mean Titers and 95% CI: SARS-CoV-2 Neutralization Assay – NT50 – Phase 2 – Dose 2 Evaluable Immunogenicity Population

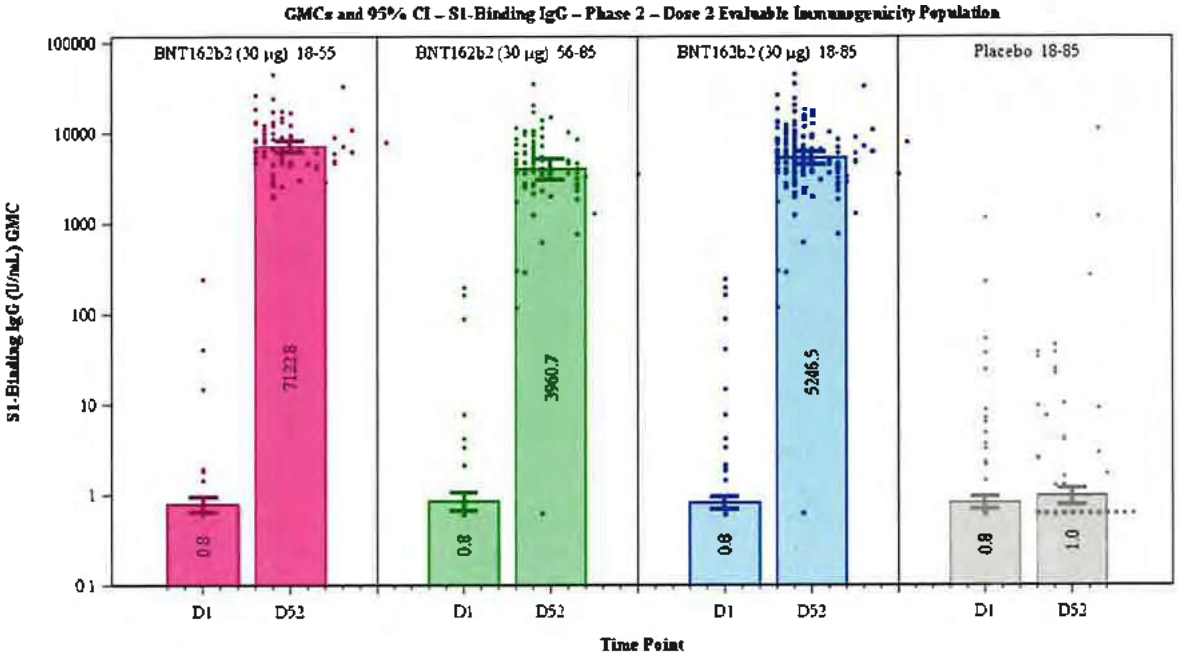

Figure 11. Geometric Mean Concentrations and 95% CI: S1-Binding IgG Level Assay – Phase 2 Dose 2 Evaluable Immunogenicity Population

A few participants in the Dose 2 evaluable immunogenicity population had a positive baseline SARS-CoV-2 status. These SARS-CoV-2 status positive participants were analysed separately from the baseline negative participants. In general, at 1 month after Dose 2 among BNT162b2 recipients, SARS-CoV-2 50% neutralizing GMTs and S1-binding IgG GMCs in participants with a positive baseline SARS-CoV-2 status (n=3) were numerically higher than those observed in participants with a negative baseline SARS-CoV-2 status (n=163).

Ancillary analyses

Vaccine Efficacy by Subgroup

For both primary endpoints, VE was also evaluated for subgroups of participants by age, sex race/ethnicity, and country, without evidence of prior infection (Table 8). Results for additional age groups are shown in Table 9.

Post hoc analyses of efficacy by risk status were performed. For these analyses, at-risk participants were defined as those who had at least one Charlson Comorbidity Index condition or who were obese (defined as BMI ≥30 kg/m2) (table 11). Results for the all-available population were similar; no clinically meaningful differences were observed in VE on the basis of subgroup.

These subgroup analyses are considered of importance. There is no evidence of significantly reduced efficacy in older age groups, i.e. >90% vaccine efficacy even in over 75-year-old subjects, although not statistically significant as there were only few cases in this age stratum. There were no cases in the 16-17-year-old age stratum, but efficacy is not anticipated to be lower in younger age groups compared to the overall study population. Additionally, it is reassuring that other factors, e.g. ethnicity/race, gender did not impact efficacy. Efficacy was not demonstrated in subjects who were

seropositive at baseline, but the subgroup was very small and results are considered inconclusive rather than negative at this stage.

Table 8 Vaccine Efficacy – First COVID-19 Occurrence From 7 Days After Dose 2, by Subgroup – Subjects Without Evidence of Infection Prior to 7 Days After Dose 2 – Evaluable Efficacy (7 Days) Population

	Vaccine Group (as Randomized)					
	BNT162b2 (30 µg) (N[a]=18198)		Placebo (N[a]=18325)			
Efficacy Endpoint Subgroup	n1[b]	Surveillance Time[c] (n2[d])	n1[b]	Surveillance Time[c] (n2[d])	VE (%)	(95% CI[e])
Overall	8	2.214 (17411)	162	2.222 (17511)	95.0	(90.0, 97.9)
Age group (years)

Abbreviations: N-binding = SARS-CoV-2 nucleoprotein–binding; NAAT = nucleic acid amplification test; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2; VE = vaccine efficacy.
Note: Subjects who had no serological or virological evidence (prior to 7 days after receipt of the last dose) of past SARS-CoV-2 infection (ie, N-binding antibody [serum] negative at Visit 1 and SARS-CoV-2 not detected by NAAT [nasal swab] at Visits 1 and 2), and had negative NAAT (nasal swab) at any unscheduled visit prior to 7 days after Dose 2 were included in the analysis.
a. N = number of subjects in the specified group.
b. n1 = Number of subjects meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted for surveillance time.
f. At risk is defined as having at least one of the Charlson Comorbidity Index (CMI) category or obesity (BMI ≥30 kg/m^2).
g. Obese is defined as BMI ≥30 kg/m^2.

Vaccine efficacy by different age subgroup is shown below in line with the information included in the SmPC.

Vaccine efficacy – First COVID-19 occurrence from 7 days after Dose 2, by age subgroup – participants without evidence of infection and participants with or without evidence of infection prior to 7 days after Dose 2 – evaluable efficacy (7 days) population

First COVID-19 occurrence from 7 days after Dose 2 in participants without evidence of prior SARS-CoV-2 infection*			
Subgroup	**COVID-19 mRNA Vaccine N[a]=18,198 Cases n1[b] Surveillance time[c] (n2[d])**	**Placebo N[a]=18,325 Cases n1[b] Surveillance time[c] (n2[d])**	**Vaccine efficacy % (95% CI)[f]**
All subjects[e]	8 2.214 (17,411)	162 2.222 (17,511)	95.0 (90.0, 97.9)
16 to 64 years	7 1.706 (13,549)	143 1.710 (13,618)	95.1 (89.6, 98.1)
65 years and older	1 0.508 (3848)	19 0.511 (3880)	94.7 (66.7, 99.9)
65 to 74 years	1 0.406 (3074)	14 0.406 (3095)	92.9 (53.1, 99.8)
75 years and older	0 0.102 (774)	5 0.106 (785)	100.0 (-13.1, 100.0)

Note: Confirmed cases were determined by Reverse Transcription-Polymerase Chain Reaction (RT-PCR) and at least 1 symptom consistent with COVID-19 [*Case definition: (at least 1 of) fever, new or increased cough, new or increased shortness of breath, chills, new or increased muscle pain, new loss of taste or smell, sore throat, diarrhoea or vomiting.]

* Participants who had no serological or virological evidence (prior to 7 days after receipt of the last dose) of past SARS-CoV-2 infection (i.e., N-binding antibody [serum] negative at Visit 1 and SARS-CoV-2 not detected by nucleic acid amplification tests (NAAT) [nasal swab] at Visits 1 and 2), and had negative NAAT (nasal swab) at any unscheduled visit prior to 7 days after Dose 2 were included in the analysis.

a. N = number of participants in the specified group.
b. n1 = Number of participants meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. No confirmed cases were identified in participants 12 to 15 years of age.
f. Confidence interval (CI) for vaccine efficacy is derived based on the Clopper and Pearson method adjusted to the surveillance time.

Vaccine efficacy for Severe COVID-19 cases, Final analysis

Among participants without evidence of SARS-CoV-2 infection before and during vaccination regimen, the estimated VE against severe COVID-19 occurring at least 7 days after Dose 2 was 66.4%, with 1 and 3 cases in the BNT162b2 and placebo groups respectively (Table 12). The posterior probability for the true vaccine efficacy greater than 30% is 74.29%, which did not meet the prespecified success criterion of >98.6% for this endpoint due to the small number of severe cases observed after Dose 2 in the study.

Consequently, statistical testing of subsequent secondary endpoints (i.e., the additional secondary endpoints related to severe disease with pre-specified control of overall type 1 error) ended. However, descriptive summaries for the additional endpoints were provided.

Table 12 Vaccine Efficacy – First Severe COVID-19 Occurrence From 7 Days After Dose 2 – Subjects Without Evidence of Infection Prior to 7 Days AfterDose 2 – Evaluable Efficacy (7 Days) Population

	Vaccine Group (as Randomized)						
	BNT162b2 (30 µg) (N[a]=18198)		Placebo (N[a]=18325)				
Efficacy Endpoint	n1[b]	Surveillance Time[c] (n2[d])	n1[b]	Surveillance Time[c] (n2[d])	VE (%)	(95% CI[e])	Pr (VE >30% | data)[f]
First severe COVID-19 occurrence from 7 days after Dose 2	1	2.215 (17411)	3	2.232 (17511)	66.4	(-124.8, 96.3)	0.7429

Abbreviations: N-binding = SARS-CoV-2 nucleoprotein–binding; NAAT = nucleic acid amplification test; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2; VE = vaccine efficacy.
Note: Subjects who had no serological or virological evidence (prior to 7 days after receipt of the last dose) of past SARS-CoV-2 infection (ie, N-binding antibody [serum] negative at Visit 1 and SARS-CoV-2 not detected by NAAT [nasal swab] at Visits 1 and 2), and had negative NAAT (nasal swab) at any unscheduled visit prior to 7 days after Dose 2 were included in the analysis.
a. N = number of subjects in the specified group.
b. n1 = Number of subjects meeting the endpoint definition.
c. Total surveillance time in 1000 person-years for the given endpoint across all subjects within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
d. n2 = Number of subjects at risk for the endpoint.
e. Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details.
f. Posterior probability (Pr) was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time. Refer to the statistical analysis plan, Appendix 2, for more details.

Summary of main study

The following table summarise the efficacy results from the main study supporting the present application. This summary should be read in conjunction with the discussion on clinical efficacy as well as the benefit risk assessment (see later sections).

Table 13 Summary of Efficacy for trial C4591001

Title: A Phase 1/2/3, Placebo-Controlled, Randomized, Observer- Blind, Dose-Finding Study to Evaluate the Safety, Tolerability, Immunogenicity, and Efficacy of SARS-COV-2 RNA Vaccine Candidates Against COVID-19 in Healthy Individuals		
Study identifier	C4591001	
Design	Phase 1/2/3 randomized, observer-blind, placebo-controlled	
	Follow-up for efficacy	Until nov 14, 2020
	Follow-up for safety	At least 1 month, median 2 months
Hypothesis	Superiority of vaccine vs placebo for vaccine efficacy	
Treatments groups	Active arm	BNT162b2 (30 µg), 2 doses, 21 days apart, randomized 22 000

	Control arm		Saline placebo, 2 doses, 21 days apart, randomized 22 000
Endpoints and definitions	First Primary endpoint	VE-7d-no-SARS-Cov-2	COVID-19 incidence per 1000 person-years of follow-up in participants without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2
	Second Primary endpoint	VE-7d-no/yes-SARS-Cov-2	COVID-19 incidence per 1000 person-years of follow-up in participants with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2.
	Secondary Endpoint	VE-14d-no-no/yes-SARS-Cov-2	COVID-19 confirmed at least 14 days after Dose 2: COVID-19 incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥14 days after Dose 2
	Secondary Endpoint	VE-7d/14d-no-no/yes-SARS-Cov-2-Severe	Severe COVID-19: incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed either (1) ≥7 days after Dose 2 or (2) ≥14 days after Dose 2
Database lock	November 14, 2020

		Pr (VE >30% |data)	0.7429
Notes	Subgroup analyses support the overall results, e.g. elderly and patients with risk factors appear to be protected as well.		

2.5.3. Discussion on clinical efficacy

Design and conduct of clinical studies

The efficacy of the selected vaccine BNT162b2 was investigated in one pivotal trial, BNT162-02 study. This is a phase 1/2/3, multicentre, multinational, randomized, placebo-controlled, observer blind, dose finding, vaccine candidate efficacy and safety study in subjects that are healthy or have clinically stable comorbidities. Safety and immunogenicity data generated during the phase 1 portion of this study supported the selection of BNT162b2 at 30 µg, as a prime/boost regimen (separated by 21 days) as the vaccine candidate to proceed into Phase 2/3.

Phase 2/3 was designed to evaluate the efficacy of BNT162b2, and to provide additional safety and immunogenicity data in a larger population. The study design for the pivotal phase 3 study is overall acceptable and in line with applicable guidelines. In the Phase 2/3 portion, approximately 44,000 participants were randomised equally and were to receive 2 doses of COVID-19 mRNA Vaccine or placebo separated by 21 days. The efficacy analyses included participants that received their second vaccination within 19 to 42 days after their first vaccination. Participants are planned to be followed for

up to 24 months after Dose 2, for assessments of safety and efficacy against COVID-19. It is an observer-blind study, which is considered acceptable as placebo and vaccine differed in appearance. Randomisation and blinding were considered acceptable.

Overall inclusion and exclusion criteria are acceptable and the study population is considered representative of the target population for vaccination, including subjects at higher risk of severe disease, i.e. age above 65 years (>20% with no upper age limit) and relevant underlying diseases (46%, e.g. obesity, chronic pulmonary diseases, diabetes, hypertension, and cardiovascular disease). Immunocompromised subjects and pregnant or breastfeeding women were excluded from the study. Subjects with known stable infection with HIV, HBV, HCV could be enrolled. Further, individuals who had previous clinical or microbiological diagnosis of COVID-19 were excluded, since the natural infection would affect the immunogenicity of the vaccine.

The study mainly recruited in the USA, but other sites worldwide were also included.

The primary endpoint (laboratory confirmed symptomatic COVID-19 in participants with no serological or virological evidence of past SARS-CoV-2 infection up to 7 days after receipt of the second dose, and then in all participants regardless of serostatus) is considered relevant for the purpose of establishing vaccine efficacy.

SARS-CoV-2 genomic RNA has been detected in nasal swab samples using Cepheid Xpert Xpress SARS-CoV-2 PCR assay on the GeneXpert Molecular Diagnostic System. This method detects 2 structural genes of SARS-CoV-2: E and N2. A validation of this method was performed, and in addition the test was issued a EUA by FDA. In order to assess the analytical detection limit, live virus and commercial control (AccuPlexTM SARS-CoV-2) were used. Clinical sensitivity and specificity were evaluated in comparison with results obtained using another FDA authorised real-time RT-PCR method with positive or negative clinical specimens and pre-pandemic samples. Results showed that Cepheid Xpert Xpress PCR assay is a sensitive and specific method for the detection of SARS-CoV-2 RNA in nasal swabs. The positive rate of self-swab is similar to site-swab, 3.7% and 4.7% positive from self-swab and site-swab respectively in the BNT162b2 group.

The third main secondary endpoint evaluated vaccine efficacy against severe cases of the disease (defined as confirmed COVID-19 with the presence of at least one of pre-defined severity criteria), to determine whether the vaccine decreased the incidence of confirmed severe COVID-19 in participants with no serological or virological evidence of past SARS-CoV-2 infection, 7 to 14 days after the second dose. Prevention of severe disease is an important endpoint, but the relative rarity of severe cases would require either a very large study population and/or a very long study duration to be certain to achieve sufficient statistical power. Therefore, it is acceptable as a secondary endpoint.

The immunogenicity secondary and exploratory endpoints are considered acceptable.

This is an event-driven study. This case-driven approach is deemed appropriate as the rate of accumulation of cases was not certain which could allow a rapid assessment of efficacy in case of a high attack rate. With assumptions of a true VE of 60% after the second dose of investigational product, a total of approximately 164 first confirmed COVID-19 illness cases will provide 90% power to conclude true VE >30% with high probability, allowing early stopping for efficacy at the IA. The randomisation procedure is considered appropriate to control confounding factors.

The statistical methods are overall acceptable. The Bayesian approach used is not expected to affect the decisions from the hypothesis testing procedure. For consistency and ease of interpretation, the Clopper Pearson confidence intervals will be included in the SmPC rather than the Bayesian credible intervals. Of the four pre-planned interim analyses only one was performed, and the final analysis was also submitted. These analyses give highly consistent results with VE far from the null hypothesis limit

of 30%. Confidence intervals were not adjusted for multiplicity, which is considered acceptable in this context.

While it could be argued that alpha could be allocated according to a group sequential design, since no failed interim analysis has been performed, the alpha allocated to the interim analysis may be recycled to the final analysis. Hence the final analysis could have been performed at full alpha level and the coverage probability of the "naïve" confidence interval is therefor considered correct.

The interim and final analyses are conducted in an evaluable efficacy population of participants who receive the two doses within the predefined window and excluding subjects with other major protocol deviation, in order to obtain a best-case estimate of vaccine efficacy. However, this approach could result in bias due to exclusion of subjects. For this reason, sensitivity analyses assessing VE based on all laboratory-confirmed cases with symptom onset at any time after the first dose (dose 1 all-available efficacy population) and 7 days after the second dose (dose 2 all-available efficacy population) have been performed without excluding participants with major protocol deviations.

Overall, the study report including the final analysis is considered adequate. This is not the final report for the study, as the study is expected to continue for a total of 24 months.

Baseline data

At the cut-off date of 14 November 2020, the disposition of the 38,000 participants were similar in the BNT162b2 and placebo groups. Overall, 0.2% of participants did not receive study vaccine. A small percentage of participants discontinued study vaccine after Dose 1 and before Dose 2 (0.6%). The reasons for discontinuation were also balanced. The most frequently reported reasons for discontinuation included: no longer meets eligibility criteria (0.3% BNT162b2; 0.4% placebo; the most common reason was previous clinical or microbiological diagnosis of COVID-19), withdrawal by participant, and AEs (0.1% in both treatment groups).

The distribution of demographics and other baseline characteristics was similar between both arms among participants without evidence of infection up to 7 days after dose 2 in the final analysis evaluable efficacy population. Overall, most participants were White (82.8%) and non-Hispanic/non-Latino (72.7%) (26.8% of Hispanic/latino ethnicity), median age was 52.0 years, and approximately 49% were female. There were 42.6% of participants in the older age group (>50 years), 26% of participants over 65 years of age and 0.7% (112 subjects) of participants adolescents (12-17 years). In 75-85 years and >85 years age groups, 837 and 5 participants respectively had been vaccinated with BNT162b2 (Dose 2 all-available efficacy).

Across both treatment groups, 20.5% had any comorbidity (per the Charlson comorbidity index). The most frequently reported comorbidities were diabetes (with and without chronic complications, 8.4%) and pulmonary disease (7.8%) and were reported at similar frequencies in each group. Obese participants made up 35.1% of the safety population. Overall, 120 subjects were HIV-positive and were evenly distributed between treatment groups.

Efficacy data and additional analyses

The population for the analysis of the primary efficacy endpoint included 36,621 participants 12 years of age and older (18,242 in the Vaccine group and 18,379 in the placebo group) who did not have evidence of prior infection with SARS-CoV-2 through 7 days after the second dose.

The first interim analysis for vaccine efficacy (VE) was conducted on 08-Nov-2020 by an IDMC. The data cut-off date was 04-Nov-2020, when a total of 94 confirmed COVID-19 cases were accrued. There were 4 COVID-19 cases in the BNT162b2 group compared to 90 COVID-19 cases reported in the

placebo group. These data gave a vaccine efficacy of 95.5% (95%CI: 88.8%, 97.5%) among participants without evidence of infection up to 7 days after Dose 2, and a >99.99% posterior probability for the true vaccine efficacy greater than 30% conditioning on available data. Participants included in the first interim analysis were also included in the final analysis.

The date for data cut-off for the final efficacy analysis was November 14, 2020, when a total of 170 confirmed COVID-19 cases were accrued.

The protective efficacy in subjects without prior evidence of SARS-CoV-2 infection from 7 days after dose 2 was high, 95.0% (95% CI: 90.0; 97.9) in the primary efficacy population (8 cases and 162 cases in the BNT162b2 and placebo groups, respectively). The posterior probability of >99.99% for the true VE greater than 30% met the pre-specified success criterion of >98.6% for this endpoint.

Among participants without evidence of SARS-CoV-2 infection before and during vaccination regimen, VE against confirmed COVID-19 occurring at least 14 days after dose 2 was 94.2%, 95%CI (88.7%, 97.2%) (8 and 139 cases in the BNT162b2 and placebo groups respectively) with a posterior probability (VE≥30%/data) of >99.99%.

Slightly more subjects in the placebo group had symptoms of COVID-19 without being a confirmed case by PCR. This is also reflected in slightly more subjects in the placebo arm with result not available from the swab. Sensitivity analysis of missing laboratory data was performed for the primary endpoint with the available data, assuming a higher than the observed case rate when imputing missing efficacy endpoints from participants in the BNT162b2 group only, to reflect potentially unknowable missing not at random (MNAR) effects that are unfavourable for efficacy results of the study. 500 imputations were performed that were generated using SAS PROC MI Fully Conditional Specification (FCS) method. Each imputation filled in the missing laboratory results based on a logistic regression model at the subject level. VE after imputation was over 80% also with up to 15-fold increase of positivity rate applied to the BNT162b2 group. Hence, there is no concern that this slight imbalance has introduced any significant bias to the results presented below.

The 2-dose schedule is considered justified both based on immune responses and on the actual efficacy results. In dose 1 all-available efficacy (mITT) population, regardless of evidence of infection before or during the vaccination regimen, 50 cases of COVID-19 occurred after Dose 1 in the BNT162b2 group (n=21,314 subjects) compared to 275 cases in the placebo group (n=21,258 subjects). Notably, in the BNT162b2 group, most cases (36/(50)) occurred before Dose 2. The estimated VE against confirmed COVID-19 occurring after dose 1 was 82% (2-sided 95% CI: 75.6 %, 86.9%), with an estimated VE of 52.4% (2-sided 95% CI: 29.5%, 68.4%) against confirmed COVID-19 occurring after dose 1 but before dose 2.

The cumulative incidence curves for the first COVID-19 occurrence after dose 1 (all-available efficacy population) showed that COVID-19 disease onset seems to occur similarly for both BNT162b2 and placebo groups until approximately 14 days after Dose 1, then cumulative curves diverge with more cases accumulating in the placebo group than in the BNT162b2 group. During the follow-up time of approximately 2 months post-dose 2, the BNT162b2 cumulative curve is stable which would not suggest waning protection. A longer follow-up is necessary to investigate the duration of the efficacy of the vaccine in protecting against the disease.

For both primary endpoints, no clinically meaningful differences in VE by subgroup were observed by age group, country, ethnicity, sex, or race in the dose 2 evaluable efficacy population, with VE estimates that ranged from 91.2% to 100.0%. Efficacy was consistent across relevant subgroups.

The results in elderly are of great importance, as increasing age is an identified risk factor for severe disease and death. The results from this study are therefore reassuring suggesting a high protective efficacy in subjects ≥65 years of age (95%, 95% CI: 66.8; 99.9). There was no indication of

decreasing efficacy in subjects ≥75 years although the number of cases was small (0 in the vaccine group and 5 in placebo). In addition, the number of subjects >85YOA is very limited (5 subjects) hence the impact of immunosenescence on vaccine efficacy in these very old individuals remain uncertain.

Among participants without prior evidence of SARS-CoV-2 infection before and during vaccination regimen, VE for participants at risk of severe COVID-19 including those with 1 or more comorbidities that increase the risk of severe COVID-19 (e.g. asthma, obese with body mass index (BMI) ≥30 kg/m2, chronic pulmonary disease, diabetes mellitus, hypertension) was 95.3%, as compared with 94.7% for those not at risk. VE for participants ≥65 years of age and at risk was 91.7%, as compared with 100% for those ≥65 years of age and not at risk. VE was similar in obese (95.4%) and non-obese (94.8%) participants. The VE by comorbidity status are as follows: cardiovascular (VE 100.0 (-0.8, 100.0)), Chronic pulmonary disease (93.0 (54.1, 99.8)), diabetes (94.7 (66.8, 99.9)), Hypertension (95.4 (82.6, 99.5)).

Severe disease cases were uncommon in the study: 1 case in the vaccine group and 4 cases in the placebo group (one case in the all evaluable population) after 7 days post second vaccination. None of the severe cases were baseline positive for SARS-CoV-2.

In the evaluable efficacy population, subjects without evidence of prior SARS-CoV-2 infection, the estimated VE against severe COVID-19 occurring at least 7 days after dose 2 was 66.4% (95% CI: -124.8%: 96.3%). The posterior probability for the true VE greater than 30% is 74.29% (7 days) and 74.32% (14 days), which did not meet the pre-specified success criterion for this endpoint, therefore no reliable conclusion can be drawn at this stage. While data on severe COVID-19 are limited, the experience with other vaccines (rotavirus and influenza vaccines with known efficacy against mild disease but better efficacy against severe disease) coupled with the high observed vaccine efficacy observed for BNT162b2 on all COVID-19 cases in populations with any comorbidity gives reassurance that the vaccine is likely to prevent severe disease. However, a precise estimate of its protective effect is presently lacking. The final study report may include additional data to the extent that the study is continued in a randomised fashion with a placebo group.

The second primary endpoint -VE in participants with and without prior evidence of SARS-CoV-2 infection- yielded similar results as the one in the population excluding those without evidence of prior infection. However, analysis is largely driven by events in subjects without evidence of prior infection, and therefore does not provide additional information.

It is not possible to conclude on vaccine efficacy in subjects with prior COVID-19, or signs of infection with SARS-CoV2 because only a small number of subjects were found to be seropositive at baseline (approximately 550 in each vaccine and placebo group), and only 2 cases of disease were reported in this subset (1 in each group). Further data may become available as the trial proceeds, but it is unlikely that the study will be able to deliver conclusive evidence for a number of reasons (e.g. it is very likely that the number of subjects seropositive will remain limited, and that there will be a lower incidence of disease in seropositive placebo recipients compared to seronegative placebo recipients due to existing partial protection). The extent of additional protection in seropositive subjects is presently uncertain. Effectiveness studies may give us some information on this regard.

Genome sequencing of the SARS-CoV-2 strains in the BNT162b2 vaccine and placebo groups has not been performed. However, this work is planned by the Applicant.

The primary analysis of efficacy was conducted when the pre-defined number of 164 COVID-19 cases had occurred. This correspond to about 1.5 months of median follow-up time duration after completion of the full vaccination regimen. Therefore, available efficacy data are limited in term of follow-up duration, and the efficacy of the vaccine over longer-time remains unknown. Data are expected to become available post-authorisation.

Immune responses in terms of neutralising antibodies were measured in the phase 1 and 2 part of the study. Overall, the immune responses measured in the phase 1 and 2 part of the pivotal study are consistent and in line with the phase 1 study BNT162-01 results. As expected, both neutralising antibody levels and S-protein binding antibody levels were higher in the youngest age stratum compared to the older age stratum. Serum titres in vaccinated subjects were numerically higher compared to human convalescent sera, up to 1 month after dose 2. There is presently no established correlate of protection.

Very limited results by baseline serostatus were provided, but updated immunogenicity data is expected to become available.

Cell mediated immune responses were demonstrated in the phase 1 part of the study as well as in the other phase 1/2 study BNT162-01, but in a small cohort of subjects only. A clear Th1-polarised response, i.e. IFNγ/IL-2 ICS and limited IL-4 ICS was shown, which is reassuring in terms of lack of VAED.

In total 14 adolescents aged 12-15 years were included in the vaccine group and 13 in the placebo group, and 52 adolescents aged 16-17 years in the vaccine and 55 in the placebo group. Vaccine efficacy could not be estimated for these subjects as no cases of disease were reported. No immune response data are available. However extrapolation of efficacy is possible from young adults because, from an immune system perspective, adolescents do not differ from young adults, thus there are no reasons to believe that the vaccine will not be as efficacious at least in the age subgroup proposed for the current indication (>16 years).

At cut-off date (14-Nov-2020), 120 subjects HIV positive were vaccinated with BNT162b2. Immunogenicity and efficacy data are not available at this time but will be provided post-authorisation.

Additional efficacy data needed in the context of a conditional MA

The final clinical study report for study C4591001 will be submitted no later than December 2023 and is subject to a specific obligation laid down in the MA.

2.5.4. Conclusions on clinical efficacy

Excellent vaccine efficacy (preventing symptomatic COVID-19) was shown in subjects without evidence of prior SARS-Cov2 infection (VE 95.0% (95% CI: 90.3%, 97.6%), which was consistent across relevant subgroups. It is likely that the vaccine also protects against severe COVID-19, though these events were rare in the study, and statistically certain conclusion cannot be drawn. It is presently not known if the vaccine protects against asymptomatic infection, or its impact on viral transmission. The duration of protection is not known.

The CHMP considers the following measures necessary to address the missing efficacy data in the context of a conditional MA:

- The final clinical study report will be submitted no later than December 2023 and is subject to a specific obligation laid down in the MA. This will provide long-term data.

Regarding missing data to confirm efficacy in subpopulations that were not studied or whose data are limited please refer to sections 2.7 and 3.3.

2.6. Clinical safety

The candidate vaccine BNT162b2 at 30 µg given twice 21 days apart was assessed a first-in-human (FIH) study in April 2020 in Germany (BNT162-01) and a Phase 1/2/3 study (C4591001) was initiated shortly afterwards in the United States (US). Hence, the safety data base for BNT162b2 constitutes of two Phase 1 studies (BNT162-01 and C4591001) and one Phase 2/3 study still ongoing (C4591001).

The cut-off for safety data included in this assessment is 14 November 2020.

The two Phase 1 trials (BNT162-01 and C4591001) are described in previous sections. Study C4591001 was initially started as a Phase 1/2 study in the USA and was then amended to expand to a global Phase 3 study.

Phase 2/3 of Study C4591001 included subjects that were stratified into two age groups: 18-55 years and >55-85 years. The Phase 3 part however was subsequently amended (6 Sept 2020 protocol amendment) to include subjects from 16 years of age in the younger age group (and then from 12 years of age) and subjects >85 years of age in the older age group.

AEs were collected during the Phase 2/3 study from the signing of the informed consensus document through and including 1 month after Dose 2 (visit no. 3). In addition, in all follow-up visits where blood samples for immunogenicity data are taken, any AEs and SAEs as appropriate occurring up to 48 hours were recorded after each visit. Immunogenicity follow-up is planned to occur during that period with visits 1-month, 6-months, 12-months and 24-months post the first vaccination. AEs are categorized by frequency, maximum severity, seriousness, and relationship to study intervention using SOC and PT according to MedDRA. SAEs are recorded for up to 6 months after Dose 2 (ongoing at the time of this submission). In addition, any potential COVID-19 illness will lead to extra visits followed by convalescent visits. At the cut-off date 14-Nov-20, the longest follow-up time available was 12-13 weeks after Dose 2 (N=780: N=382 BNT162b2 and N=398 placebo).

Overall the study enrolled Phase 2/3 participants (N=43,448) that received at least one dose of BNT162b2 (N=21,720) or placebo (N=21,728), regardless of duration of follow-up.

The assessment is based on the following safety data (cut-off date 14 Nov 2020):

- Phase 1: i) Study C4591001 (N=72 any dose of BNT162b2; N=12 BNT162b2 30µg; placebo N=18); ii) Study BNT162-01 (N=60 any dose of BNT162b2; N=12 BNT162b2 30µg; placebo N=0).
- Phase 2/3 participants with a follow-up ≥ 2 months after Dose 2 (N=19,037) of either BNT162b2 (N=9531) or placebo (N=9536). This subset constitutes the core safety data set in this assessment.
- All enrolled Phase 2/3 participants (N=43,448) that received at least one dose of BNT162b2 (N=21,720) or placebo (N=21,728), regardless of duration of follow-up. In this population, the total number of subjects 16-17 years were 283 (N=138 BNT162b; N=145 placebo) and 100 participants were 12 to 15 years of age (N=100; 49 in the BNT162b2 group and 51 in the placebo group).
- Phase 2/3 participants (N=37,706) randomised before 9 October 2020 who received BNT162b2 (N=18,860) or placebo (N=18,846). These subjects had a median follow-up time of 2 months after Dose 2 (at least 1 month after dose 2). Among these, 1,148 subjects had a positive SARS-CoV-2 baseline status (vaccinated N=558; placebo N=590).
- Reactogenicity was evaluated based on a subset of subjects in the Phase 2/3 study, i.e. 8,183 (N=4,093 BNT162b2; N=4,090 placebo), who reported on local reactions, systemic events,

and antipyretic/pain medication usage for 7 days after each dose by using an e-diary. Eight subjects aged 16-17 years were included in this subset (BNT162b2 N=5; placebo N=3).

2.6.1. Patient exposure

Distribution and Exposure were presented for the population with median follow up of 2 months and for the whole population. Of the 37,796 subjects in the group with median follow up of 2 months who were randomized in the study before 9 October 2020, 90 participants (0.2%) were excluded from the safety population (89 did not receive study intervention and 1 did not provide informed consent).

		BNT162b2 N = 18904	**Placebo N = 18892**
		N (%)	**N (%)**
Median follow up 2 months (at least one month after dose 2)	Randomized	18904 (100%)	18892 (100%)
	Vaccinated with Dose 1	18858 (99.8%)	18849 (99.8%)
	Vaccinated with Dose 2	18553 (98.1)	18534 (98.1%)
HIV positive		59	61
Follow up ≥ 2months after dose 2		9531 (50.5%)	9536 (50.6%)
Follow up ≥ 10 to < 12 weeks after dose 2		2853 (15.1%)	2809 (14.9%)
Follow up ≥ 12 to < 14 weeks after dose 2		382 (2.0%)	398 (2.1%)

For Dose 1, three participants randomized to the placebo group received BNT162b2, and two participants randomized to the BNT162b2 group received placebo. For Dose 2, four participants randomized to the placebo group received BNT162b2, and five participants randomized to the BNT162b2 group received placebo.

The majority of participants received Dose 2 between 19 to 23 days after Dose 1 in the BNT162b2 (93.1%) and placebo (92.9%) groups.

Overall, 0.3% of participants were HIV-positive and were evenly distributed between treatment groups. Note that HIV-positive participants were included in the safety population and are shown as part of the study demographics and disposition but did not have safety data available to contribute to the safety analyses at the time of the data cut-off.

In total 1145 individuals of the safety population were SARS-CoV-2 seropositive at baseline.

A high exposure rate of 99.8% to the first dose was reached in both vaccine and control arm and a small number of individuals were withdrawn after the first dose, leading to a high rate of exposure to the second dose in both study arms (98.2% and 98.1%). Reasons for withdrawals (1.0% and 1.4%, respectively) were in most cases withdrawals by the participant, or loss to follow-up.

There were no clinically meaningful differences in the safety population by age group, baseline SARS-CoV-2 status, ethnicity, race, or sex.

Table 14 Safety Population, by Baseline SARS-CoV-2 Status – ~38000 Subjects for Phase 2/3 Analysis

		Vaccine Group (as Administered)		
Baseline SARS-CoV-2 Status		BNT162b2 (30 µg) n[a]	Placebo n[a]	Total n[a] (%)
Positive	Randomized[b]			1148
	Vaccinated	557	588	1145 (99.7)
	Safety population	557	588	1145 (99.7)
	HIV-positive	12	8	20 (1.7)
	Excluded from safety population			3 (0.3)
	Reason for exclusion			
	Subject did not receive study vaccine			3 (0.3)
Negative	Randomized[b]			35764
	Vaccinated	17885	17858	35743 (99.9)
	Safety population	17884	17858	35742 (99.9)
	HIV-positive	43	50	93 (0.3)
	Excluded from safety population			22 (0.1)
	Reason for exclusion			
	Subject did not receive study vaccine			21 (0.1)
	Did not provide informed consent			1 (0.0)

Note: HIV-positive subjects are included in this summary but not included in the analyses of the overall study objectives.
Note: Subjects whose baseline SARS-CoV-2 status cannot be determined because of missing N-binding antibody or NAAT at Visit 1 were not included in the analysis.
Note: Positive = positive N-binding antibody result at Visit 1, positive NAAT result at Visit 1, or medical history of COVID-19. Negative = negative N-binding antibody result at Visit 1, negative NAAT result at Visit 1, and no medical history of COVID-19.
a. n = Number of subjects with the specified characteristic, or the total sample.
b. This value is the denominator for the percentage calculations.

The disposition, exposure and withdrawal profile of the whole study population was comparable to the group that was randomised before 9 October 2020 with median follow up of 2 months.

Among the 37,706 subjects with a median follow-up of 2 months, 50.6% had ≥2 months duration of follow-up after Dose 2 and 91.6% had a duration of follow-up time of ≥1 month after Dose 2. Around 3000 individuals have already a follow of at least 10 weeks after dose 2. Updates, including additional safety data as well as assessment of the differences in safety profile in the longer follow-up compared to the initial safety dataset, if any, shall be provided when more mature data will be available.

Six-months post Dose 2 follow-up data from the first ~6000 subjects are expected by the end of February 2021 and this will allow a relevant discussion on the safety profile versus the initial dataset.

Based on the population with a median follow up of 2 months, demographic characteristics are considered well balanced between vaccine and placebo arm. Most included subjects were white (83%), with a median age of 52 years. A balanced distribution is seen regarding gender (51% male, 49%

female). The younger and older age groups were 57.8% and 42.2% of participants, respectively. Within each age group, most demographic characteristics were similar in the BNT162b2 and placebo groups. Of note, 35% of individuals were obese in both study arms. Across both treatment groups, 20.7% had any comorbidity.

The number of subjects with any Charlson co-morbidity diagnoses was balanced in both study arms (20%). Most prevalent were the diagnoses diabetes mellitus (7.8%) and COPD (7.8%) followed by subjects showing any type of malignant disease (3.9% in vaccine and 3.5% in placebo group). Other diagnoses were abundant with ≤ 1% in both study arms (population with a median follow up of 2 months). In the population with a follow-up ≥2 months, Charlson co-morbidity diagnoses was similar.

The demographic distribution was somewhat different when comparing seropositive and seronegative individuals, observing a median age of 43 years in seropositive and of 52 years in seronegative individuals. Furthermore, the seropositive group covered a higher proportion of obese individuals (42.2% versus 34.7%). Demographic characteristics in the whole population were comparable to those seen in the population with a median follow up time of 2 months.

2.6.2. Reactogenicity

Reactogenicity was evaluated in a subset of the Phase 2/3 study of 8,183 subjects (BNT162b2 n=4093; placebo n=4090) from both age groups (16 to 55 and >55 years of age) that received BNT162b2 or vaccine according to the proposed dosing regimen. Of note, the number of subjects aged 16-17 years included in this subset was limited (n=8; BNT162b2 n=5; placebo n=3). After each dose, the subjects reported any local reactions, systemic events, including antipyretic/pain medication usage for 7 days, by using an e-diary (cut-off date 14 Nov 20).

Local reactions

The most commonly reported local reaction among the subject that received BNT162b2 was pain at the injection site, which occurred slightly more common among subjects 16-55 years (N=2291 [83.1%] post Dose 1; N=2098 [77.8%] post Dose 2) compared to those >55 years of age (N=1802 [71.1%] post Dose 1; N=1660 [66.1%] post Dose 2). In the placebo group, pain at the injection site after Doses 1 and 2 was reported at a lower frequency (16-55 [14.0% and 11.7%]; >55 [9.3% vs 7.7%]).

There was no difference in frequency of redness and swelling at injection site after the two doses of BNT162b2. Redness occurred in about 5-7% in both age groups (16-55 [4.5% after Dose 1, 5.9% after Dose 2]; >55 [4.7% after Dose 1, 7.2% after Dose 2]). Swelling was reported also in about 5-7% of the subjects in both age groups (16-55 [5.8% after Dose 1, 6.3% after Dose 2]; >55 [6.5% after Dose 1, 7.5% after Dose 2]). In the placebo group, redness and swelling were reported infrequently in both age groups (≤1.2%).

Overall, the majority of local reactions were mild or moderate in severity, no Grade 4 reactions were reported. Severe local reactions (≤0.7%) were reported infrequently in the BNT162b2 group after either dose and was more commonly reported in the younger group. Across age groups, local reactions for the BNT162b2 group after either dose had a median onset between 1-3 days (Day 1 was the day of vaccination), with a median duration of 1-2 days.

No clinically meaningful differences in local reactions were observed by baseline SARS-CoV-2 status subgroups. However, since the baseline SARS-CoV-2 positive subgroup included very few participants (vaccinated n=154; placebo n=164), these results should be interpreted with caution.

Systemic reactions

Table 15 Subjects Reporting Systemic Events, by Maximum Severity, Within 7 Days After Each Dose, Age Group 16-55 Years – Reactogenicity Subset for Phase 2/3 Analysis– Safety Population

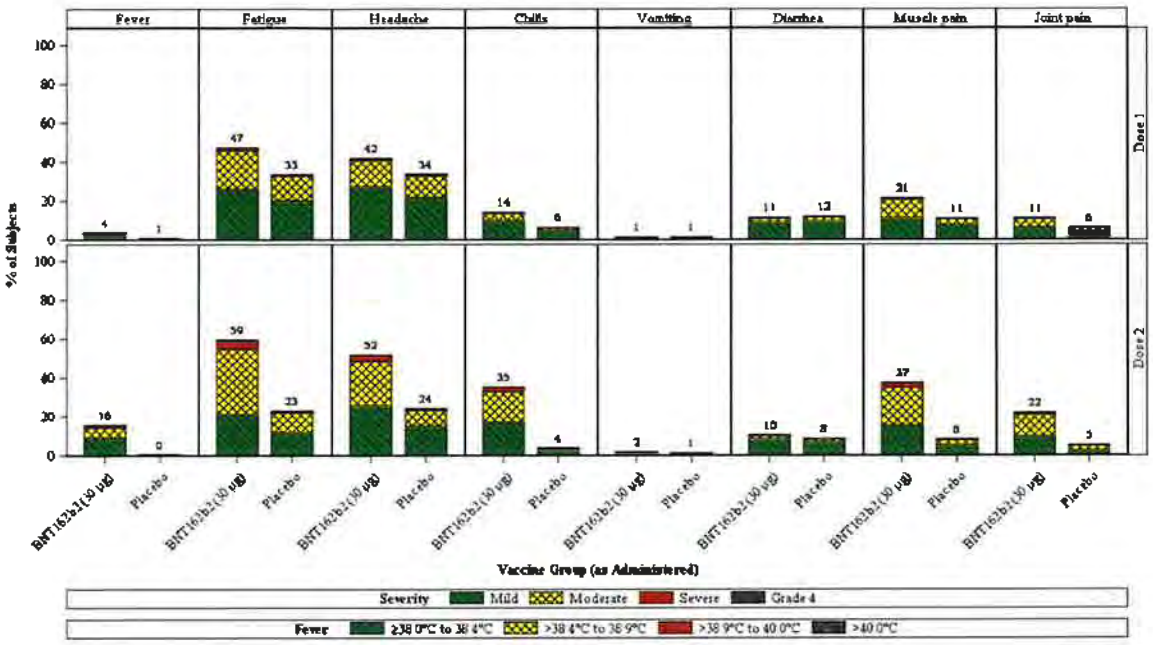

Table 16 Subjects Reporting Systemic Events, by Maximum Severity, Within 7 Days After Each Dose, Age Group >55 Years – Reactogenicity Subset for Phase 2/3 Analysis–Safety Population

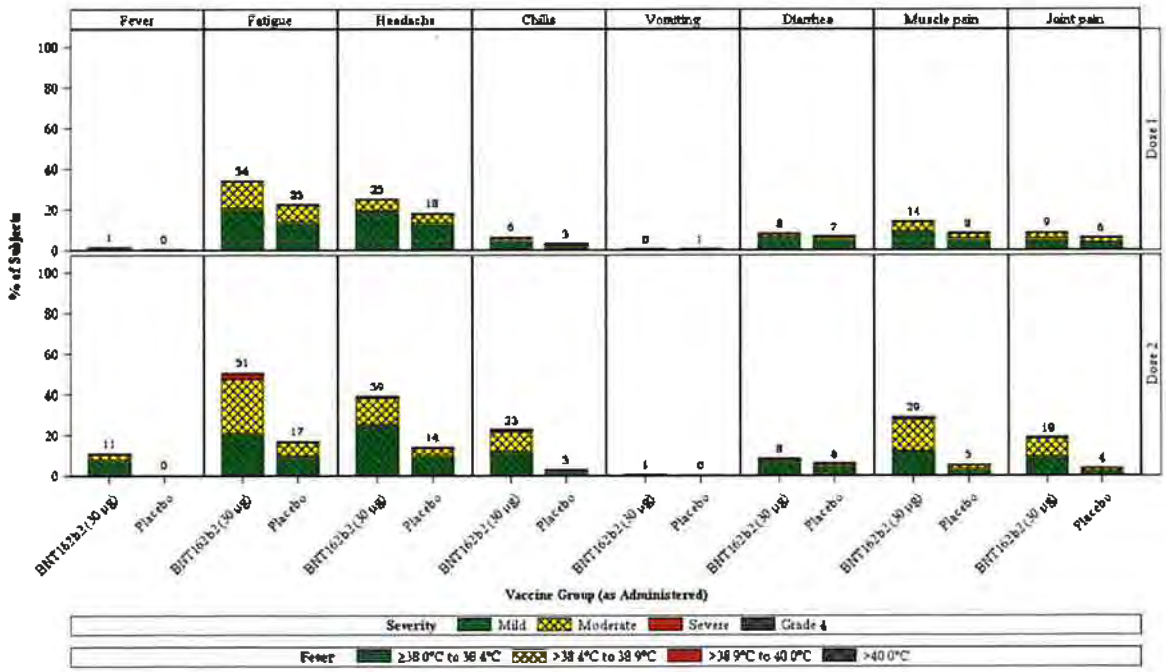

Systemic events were generally reported more frequently in the BNT162b2 group than in the placebo group, for both age groups and doses. Across age groups, median onset day for all systemic events after either dose of BNT162b2 was 2-3 days, with a median duration of 1 day.

Systemic events were generally increased in frequency and severity in the younger age group compared with the older age group, with frequencies and severity increasing with number of doses (Dose 1 *vs* Dose 2). Vomiting and diarrhoea were exceptions, with vomiting reported similarly infrequently in both age groups and diarrhoea reported at similar incidences after each dose. Systemic events in the younger group compared with the older group, with frequencies increasing with number of doses (Dose 1 vs Dose 2), were: fatigue, headache, muscle pain, chills, joint pain and, fever.

Following both Dose 1 and Dose 2, use of antipyretic/pain medication was slightly less frequent in the older age group (19.9% vs 37.7%) than in the younger age group (27.8% vs 45.0%). Of note, medication use increased in both age groups after Dose 2 as compared with after Dose 1. Use of antipyretic/pain medication was less frequent in the placebo group than in the BNT162b2 group and was similar after Dose 1 and Dose 2 in the younger and older placebo groups (ranging from 9.8% to 22.0%).

No clinically meaningful differences in systemic reactions were observed by baseline SARS-CoV-2 status subgroups, however as mentioned data in baseline SARS-CoV-2 positive subjects are limited.

Overall, the reported reactogenicity is in line with what can be expected from any vaccine. The local and systemic reactions were transient and of short duration, the majority were mild to moderate at intensity and the reactions were milder among older subjects (>55 years).

2.6.3. Adverse events

In the subset of participants randomised before 9 October 2020 with Median 2 Months of Follow-Up After Dose 2 (N= 37,586; from Dose 1 to 1 month after dose 2) and the subset of participants with at least 2 Months of Follow-Up After Dose 2 (N=19,067; from dose 1 to data cut off 14 November 2020), the numbers of overall participants who reported at least 1 AE and at least 1 related AE were higher in the BNT162b2 group as compared with the placebo group. This trend continued to be seen through the data cut-off date for all enrolled participants (N=43,252; from dose 1 to data cut-off 14 November 2020). Overall, AEs reported from Dose 1 to 7 days after Dose 1 and from Dose 2 to 7 days after Dose 2 were largely attributable to reactogenicity events (see above). This observation provides a reasonable explanation for the greater rates of AEs observed overall in the BNT162b2 group (26.7%) compared with the placebo group (12.2%).

Among all 43,448 enrolled participants included in the safety database up to the data cut-off date, few participants in the BNT162b2 group (0.2%) and in the placebo group (0.1%) were withdrawn because of AEs.

Table 17 Number (%) of Subjects Reporting at Least 1 Adverse Event from Dose 1 to date cutoff date (14 Nov 2020) – Subjects with 2 months follow-up time after dose 2 for Phase 2/3 Analysis – Safety Population

	Vaccine Group (as Administered)

a. N = number of subjects in the specified group. This value is the denominator for the percentage calculations
b. n = Number of subjects reporting at least 1 occurrence of the specified event category. For "any event", n = the number of subjects reporting at least 1 occurrence of any event.
c. Assessed by the investigator as related to investigational product

PFIZER CONFIDENTIAL SDTM Creation: 17NOV2020 (09:48) Source Data: adae Table Generation: 17NOV2020 (16.28)
(Cutoff Date: 14NOV2020, Snapshot Date: 16NOV2020) Output File:
./nda2_unblinded/C4591001_IA_P3_2MPD2/adae_s091_all_2mpd2_p23_saf

Overall, in participants with 2 months follow up after dose 2, 21.4% / 12.6% (vaccine/placebo) and 13.6%/3.6% experienced at least 1 AE and 1 related AE, respectively. It is noted that the frequency of AEs and related AEs is lower compared to individuals with a median follow up of 2 months (27%/12.5% and 20.8%/5.1%).

The frequency of individuals experiencing AEs were slightly higher in the younger compared to older individuals (29.3% and 23.8% vaccine arm; 13.2% and 11.7% placebo arm). SAEs and deaths were however balanced in both study arms in both age groups.

The frequency of immediate AEs after dose 1 was low in participants with median 2 months of follow-up after Dose 2 (0.4%) and the whole population (≤0.5%), belonging mostly to the SOC general disorders and administration site conditions, primarily injection site reactions. No participant reported an immediate allergic reaction to vaccine.

Severe AEs, SAEs, AEs leading to discontinuation, and deaths were reported by ≤1.1%, 0.6%, 0.0%, and 0.0%, i.e. low and equally distributed in both study arms. No differences vs. the whole population were seen according to age groups.

The rate of AEs and related AEs was slightly higher in the SARS-CoV-2 negative group compared to SARS-CoV-2-positive individuals. Stratification according to serostatus in the safety group median follow up 2 months reveals overall very low numbers of severe AEs, SAEs and deaths.

Table 18 Number (%) of Subjects Reporting at Least 1 Adverse Event from Dose 1 to 1 Month after Dose 2, by Baseline SARS-CoV-2 Status - ~38000 Subject for Phase 2/3 Analysis – Safety Population Baseline SARS-CoV-2 Status: Positive

	Vaccine Group (as Administered)

PFIZER CONFIDENTIAL SDTM Creation: 17NOV2020 (09:48) Source Data: adae Table Generation: 17NOV2020 (16:29)
(Cutoff Date: 14NOV2020, Snapshot Date: 16NOV2020) Output File: ./nda2_unblinded/C4591001_IA_P3_2MPD2/adae_s091_pd2_bs_p3_saf

There were 19,067 participants with at least 2 months follow-up time after Dose 2, and similar to the 37,586 participants randomised before 9 October 2020 with a median of 2 months of safety follow up after Dose 2, most AEs reported after Dose 1 up to the safety data cut-off date were reactogenicity, in SOCs of:

- general disorders and administration site conditions (11.9% BNT162b2 vs 2.9% placebo)
- musculoskeletal and connective tissue disorders (5.5% BNT162b2 vs 2.1% placebo)
- nervous system disorders (4.2% BNT162b2 vs 2.1% placebo)
- infections and infestations (1.9% BNT162b2 vs 1.6% placebo)
- gastrointestinal disorders (2.6% BNT162b2 vs 1.8% placebo).

In the younger versus older BNT162b2 age groups, AE SOCs were:

- general disorders and administration site conditions (13.1% vs 10.4%)
- musculoskeletal and connective tissue disorders (6.0% vs 4.9%)

- nervous system disorders (4.8% vs 3.5%)
- infections and infestations (1.9% vs 1.9%)
- gastrointestinal disorders (2.7% vs 2.5%)

Most often occurring events by PT comprised vaccine typical reactions such as injection site pain, fever, fatigue as well as myalgia and arthralgia. Lymphadenopathy and nausea occurred respectively in 0.4% and 0.6% more cases in the vaccine compared to placebo arm.

Related AEs belonged overall to the same SOCs as described above, i.e. general disorders and administration site conditions (3426 cases, 20.8%), musculoskeletal reactions (1148 cases, 6.1%), and nervous system disorders (979 cases, 5.2%) and occurred overall more often in the vaccine than in the placebo arm (median follow up 2 months). Severe AEs occurred more often in the vaccine arm (1.2% vs. 0.6%) in the subset with a median follow up time of 2 months, reflecting a similar SOC pattern.

The following specific observations are made based on PTs:

Numerical disbalances are observed for several hypersensitivity terms ((drug)hypersensitivity/ immunisation events; 5/3 cases ≥ 2 months group, 13/6 cases whole population, 6/1 cases deemed related in the whole population, 4 cases deemed severe (whole population), in the SOC immune system disorders).

Subjects were excluded from the Phase 2/3 study if they had a history of severe adverse reaction associated with a vaccine or to any component of the BNT162b2 vaccine. The protocol did not exclude individuals with non-severe allergic reactions to other vaccines or individuals with an allergic reaction, of any severity, to medication, food or environmental allergies.

In the Phase 2/3 study, 11,673 subjects had a medical history of allergic condition (n=5839 BNT162b2; n=5834 placebo), and, among those, two cases of allergic AEs (1 in each treatment group) occurred, which were deemed related to study treatment by the investigator. The participant who received BNT162b2 had a history of allergy to tree pollen. This participant reported Drug hypersensitivity and Urticaria on the day of Dose 1. Both AEs were of moderate severity and lasted one day. The participant did not receive Dose 2 of the vaccine. The participant who received placebo had an allergy to shellfish and iodine. This participant reported Allergy to vaccine and Pharyngeal swelling 1 day after Dose 1. Both events were of moderate severity and lasted 13 days and 10 days, respectively. This participant did not receive Dose 2 of study intervention.

In the ~38,000 study participants with a median of 2 months of safety follow-up after Dose 2, none reported an immediate AE (occurring within 30 minutes after dosing) that was indicative of an allergic reaction to vaccine.

Four cases of facial paralysis were observed in the vaccine arm (facial paralysis [n=4 BNT162b2; n=0 placebo] facial paresis [n=0 BNT162b2; n=1 placebo] in total 4/1 whole population). Time to onset after injection with BNT162b2 was 3, 9 and 48 days after Dose 2 and 37 days after Dose 1, which suggest a possible association with the vaccination. The two subjects with a time to onset of 3 and 9 nine days had no previous history of Bell´s palsy, both subjects improved with prednisolone and the events were also deemed related to study intervention by the study physician.

Numerical imbalances in AEs for appendicitis and biliary events are observed (8/4 and 14/5 cases (whole population)). However, none of the cases considered related to study drug treatment.

Cases of (osteo/peri) arthritis (15/15, vaccine/placebo) and psoriasis (1/1, vaccine/placebo) have been observed in the vaccine arm, which where however balanced in frequency between vaccine and placebo arm.

An imbalance in PT connected to sleep disturbances was noted in the whole population, which was driven by 25 more cases of insomnia-related events (insomnia/sleep disorder/abnormal dreams in the BNT162b2 group versus the placebo arm).

A slight imbalance of hyperhidrosis/night sweats was noted in the whole population (n=26/15 BNT162b2 group versus 8/3 in the placebo arm). Hyperhidrosis as a medical term indicates a condition that differs from the sweating associated with episodes of fever. The numerical relation here is not supported by biological plausibility.

Injection site pruritus was reported in 31 subjects in the BNT162b2 group compared to 6 subjects in the placebo arm (whole population).

Pain in the extremity was reported in 183 subjects in the BNT162b2 group and in 34 subjects in the placebo group (whole population).

Stratification according to age did not reveal meaningful differences in the types of AEs.

A stratification according to serostatus was performed in individuals with a follow up of at least one month (median FUP 2 months) and ≥2 months. Most abundant SOCs are similar to the SOCs identified in the general population with ≥2 months follow-up. No additional safety concerns are detected when stratifying according to serostatus.

2.6.4. Serious adverse event/deaths/other significant events

SAEs

This section presents the SAEs reported up to the data cut-off (14-nov-20).

Among the 19,067 subjects (BNT162b2 n=9531; placebo n= 9536) with ≥2 months of follow-up post Dose 2, small percentages of subjects in the 30 µg BNT162b2 group (56 [0.6%]) and the placebo group (53 [0.6%]) reported any SAEs. Subjects in both the BNT162b2 group and placebo group, respectively, reported SAEs at similar rates for the observed SOCs. A similar frequency was observed for the entire study population and no clinically meaningful differences in SAEs were observed by age, baseline SARS-CoV-2 status, ethnicity, race or sex subgroups.

Among all included subjects (BNT162b2 n=21720; placebo n=21728) three SAEs were reported in the SOC immune system disorders. One SAE of anaphylactic reaction (related to bee sting) and one drug hypersensitivity (related to treatment with doxycycline) was reported in the BNT162b2 group. In addition, one SAE of anaphylactic shock (related to an ant bite) was reported in the placebo group.

In the subset of individuals aged 16-17 years old, one SAE (facial bone fracture) was reported.

After the cut-off date and up to 5-Dec-20, additional 22 SAEs have been reported (blinded data).

SAEs related to study intervention

Up to the cut-off date, four of the SAEs in the BNT162b2 group and none in the placebo group were assessed by the investigator as related to study intervention. One event of lymphadenopathy and one event of shoulder injury due to incorrected administration were considered related to BNT162b2.

It is not agreed that the event of ventricular arrythmia and the event of pain in the lower back/extremities/and radicular paraesthesia have been convincingly demonstrated to be related to study intervention, since the subjects had underlying conditions that could have caused the two SAEs, there is little biological plausibility, and the overall numbers of reported events do not allow for a causal inference.

Death

Six events of death (2 in the BNT162b2 group and 4 in the placebo group) were reported in the Phase 2/3 study up to the cut-off date of 14-Nov-20. None of the deaths were considered related to study intervention, which is agreed since other pre-existing diseases were more likely to have caused death than the vaccine. After the cut-off date and up to 5-Dec-20, one additional event of death due to aortic rupture were reported (data blinded).

2.6.5. Laboratory findings

Laboratory results are available for the two Phase 1 studies, but not for the Phase 2/3 trials. This is considered acceptable. Except for minor transient decrease in lymphocyte count observed for some of the subjects, no abnormal lab results were reported from the Phase 1 studies.

2.6.6. Safety in special populations

No clinically meaningful differences in AEs were observed by age, country (mostly Argentina, Brazil, USA), ethnicity (Hispanic/Latino, Non-Hispanic/Non-Latino), gender and race (With, Black or African American, all other races) subgroups.

Pregnancy

At the time of the data cut-off in the Phase 2/3 study (14 Nov 2020), a total of 23 participants had reported pregnancies in the safety database, including 9 participants who withdrew from the vaccination period of the study due to pregnancy. These participants are being followed for pregnancy outcomes. Thus, data on pregnancy are very limited at this stage.

Elderly

The Phase 2/3 study included >40% of subjects >55 years of age. In general, reactogenicity and AE rate were slightly lower in older compared to younger individuals (stratified according to median age 55 years). No differences in AE frequency were detected among subjects >70 years of age compared to the older age group >55 year. Thus, no specific safety concern is anticipated for the elderly.

Immunocompromised individuals

Per protocol, participants with chronic stable HIV infection were defined as HIV disease with a documented viral load <50 copies/mL and CD4 count >200 cells/mm3 within 6 months before enrolment, and on stable antiretroviral therapy for at least 6 months. Stratification by CD4 count, efficacy and immunogenicity data are not available at this time but will be provided post-authorisation.

Safety data are available for 196 participants with stable HIV infection. The most frequent AEs in the BNT162b2 group were reported in the General Disorders and Administrative Site Conditions SOC including injection site pain, pyrexia, chills, fatigue, injection site erythema, and injection site swelling.

Assessment of paediatric data on clinical safety

Paediatric individuals age 16 to 17 years of age are included in the Phase 2/3 study that constitutes the safety database in this assessment. The population of subjects aged 16-17 years are limited (n=283). No additional or new AEs were observed compared to adults).

There were no participants in the 16 to 17 years of age group with ≥2 months of safety follow-up at the time of the data cut-off (14 November 2020). The longest duration of follow-up in this age group, at the time of the data cut-off, was 39 days after Dose 2. The adverse event profile for this adolescent age group did not show meaningful differences vs. the young adult group (18 to 55 years of age) in the study.

The reactogenicity subset of ~8000 participants (n=4093 BNT162b2; n=4090 placebo) contributing e-diary data included a total of 8 participants in the 16 to 17 years of age group (including participants in both the BNT162b2 group and the placebo group).

Available safety data for participants 12 to 15 years of age (N=100; n=49 BNT162b2; n= 51 placebo, as recruited in the Phase 2/3 study under protocol amendment 7) include reactogenicity data (local reactions and systemic events) collected via e-diary up to the safety cut-off date of 14 November 2020. The reported adverse events were primarily reactogenicity events with no serious adverse events. The local reactogenicity profile seems comparable with the young adult population, with however a higher systemic reactogenicity as compared to young adults.

In the reactogenicity subset including individuals aged 12-15 years and the 8 individuals aged 16-17 years, the most frequently reported systemic reaction in both treatment groups were fatigue (59.2% in the BNT162b2 group and 25.5% in the placebo group), followed by headache (57.1% BNT162b2, 43.1% placebo). Fever ≥38°C was reported for 26.5% more participants who received BNT162b2 over placebo; two (4.1%) of these participants reported severe fever (>38.9°C to 40.0°C).

2.6.7. Safety related to drug-drug interactions and other interactions

Interaction studies with other vaccines have not been performed, which is acceptable given the need to use the vaccine in an emergency situation. The Applicant will conduct a study post-authorisation as indicated in the RMP (see section 2.7).

2.6.8. Discontinuation due to adverse events

Among all 43,448 enrolled participants included in the safety database up to the data cut-off date, few participants in the BNT162b2 group (0.2%) and in the placebo group (0.1%) were withdrawn from the study because of AEs. The results were similar to the AEs leading to withdrawal in the group randomised before 9 October 2020 with median follow up of 2 months. Among 19,067 participants with at least 2 months of follow-up time post Dose 2, 1 participant in the BNT162b2 group and no participants in the placebo group had an AE leading to withdrawal from the study.

No participants in the 16 to 17 years of age group experienced an AE leading to withdrawal. Among all 43,448 participants, no clinically meaningful differences in AEs leading to withdrawal were observed by age or other subgroups.

2.6.9. Post marketing experience

Post-marketing data are not yet available as the vaccine has not been approved in any country at the time of the data cut-off (14-Nov-20). After the cut-off date, it is noted that several countries have recently authorised the vaccine for emergency use (e.g. UK, Canada, US). Two cases of anaphylactoid reaction out of 138,000 persons vaccinated have been reported in individuals carrying Epipen after initiation of vaccination in one country, which resolved with standard therapy. One case of anaphylaxis was reported in another country (unknown denominator) in a subject without known history of

allergies, which required ICU and was then resolved. Post-marketing safety data are expected with the next monthly summary safety report.

2.6.10. Discussion on clinical safety

The safety database for BNT162b2 constitutes of two Phase 1 studies (BNT162-01[3] and C4591001[4]) and one Phase 2/3 study (C4591001) which is still ongoing. The cut-off date for safety data included in this assessment is 14 November 2020.

Up to the cut-off date ~44,000 subjects had been recruited and received at least one dose of either BNT162b2 (n=21,720) or placebo (n=21,728). The core safety database of this assessment constitutes of ~19,000 participants who have been followed ≥2 months after the 2nd dose of BNT162b2 (n=9531) or placebo (n=9536). The Applicant has also presented data from a subset of ~38,000 subjects randomised before 9 October 2020 with a median follow-up period of 2 months after Dose 2 of BNT162b2 (n=18,860) or placebo (n=18,846).

Demographic characteristics are considered well balanced between vaccine and placebo arm (median follow up 2 months). Subjects were mostly white (83%) and had a median age of 52 years. The younger and older age groups included 57.8% and 42.2% of participants, respectively. Within each age group, most demographic characteristics were similar in the BNT162b2 and placebo groups. Gender was balanced (51% male). Of note, 35% of individuals were obese in study arms. The demographic distribution was different between seropositive and seronegative individuals, with a median age of 43 years in seropositive and of 52 years in seronegative subjects. Furthermore, the seropositive group covered a higher rate of obese individuals (42.2% versus 34.7%). Demographic characteristics in all participants were roughly comparable to those with median follow up of 2 months.

Charlson co-morbidity diagnoses were balanced in both study arms (20%). Most prevalent co-morbidities were diabetes (7.8%), COPD (7.8%) and malignant disease (3.9% in the vaccine arm and 3.5% in the placebo arm). Other diagnoses accounted for ≤ 1% of subjects in both study arms (median follow up of 2 months).

In the Phase 2/3 study reactogenicity was evaluated in a subset of 8,183 subjects who received BNT162b2 (n=4093) or placebo (n=4090) according to the proposed dosing regimen. The number of subjects aged 16-17 years included in the reactogenicity subset was small (n=8; BNT162b2 n=5; placebo n=3). After each dose, all subjects were asked to report any local reactions, systemic events, and antipyretic/pain medication usage for 7 days, by using an e-diary.

Pain at the injection site was the most common local reaction reported in the vaccine group, slightly more frequently reported among subjects 16-55 years (~80%) compared to >55 years (~70%). In the placebo group 8-14% reported pain at injection site. In the vaccine group redness and swelling were overall reported at a frequency of 5-7% in both age groups (vs. placebo 0-1%). Use of antipyretic/pain medication was more common after Dose 2 than after Dose 1 in both age groups, and overall slightly lower among subjects >55 years regardless of the dose (younger group: 28% after dose 1 vs 45% after dose 2; older group: 20% vs 38%). The use of antipyretic/pain medication was less common in the placebo group (younger group: 34% after dose 1 vs 23% after dose 2; older group: 23% vs 18%).

Among the systemic reactions, headache and fatigue were the most common events, and the frequency was higher after Dose 2 compared to Dose 1 (16-55 YOA [47% vs 59%]; >55 YOA [34% vs 51%]). Fever also occurred more frequently after Dose 2 (16-55 YOA [4% vs 16%]; >55 YOA [1% vs

[3] Phase I: End of study 28 days after Dose 2.
[4] Phase I: participants enrolled in Phase1 in groups that do not proceed to Phase 2/3 (i.e. other doses than 30 µg) may be followed for fewer than 24 months (but no less than 6 months after the last vaccination).

11%]). None of the subjects >55 YOA in the placebo group reported events of fever and 1% of the subjects aged 16-55 years reported fever after the first dose.

Overall, the local and systemic reactions were transient and of short duration (resolved within few days after vaccination), the majority were of mild to moderate intensity, and milder and of slightly lower frequency among older subjects (>55 years of age).

In the group of 19,067 participants with 2 months follow up after dose 2, 21.4% and 12.6% (vaccine vs placebo) of the subjects reported at least one AE. 13.6%/3.6% reported at least 1 related AE. Rates were lower compared to the whole enrolled trial population (26.7% (vaccine) and 12.2% (placebo)).

AEs in subjects with a follow up of at least 2 months belonged most often to the SOCs "General disorders and administration site conditions" (11.9% vs 2.9%), "musculoskeletal reactions" (5.5% vs 2.1%), and "nervous system disorders" (4.2% vs 2.1%), occurring more often in the vaccine than in the placebo arm. PTs comprised most often vaccine typical reactions, i.e. injection site pain, redness and swelling, fever, chills, fatigue, headache as well as myalgia and arthralgia and malaise. Nausea also occurred more often in the vaccine arm (79 cases, i.e. 0.8%, in vaccine vs. 21 cases, i.e. 0.2%, in placebo). Lymphadenopathy was seen in 0.4% subjects in the vaccine arm (38 cases) vs. 0% in the placebo arm (3 cases).

Severe AEs were reported by a small number of subjects (≤1.1%) and equally distributed between the study arms. No differences were seen between age groups. Frequencies are comparable in the whole enrolled trial population and when stratifying according to serostatus.

Numerical imbalances are observed for several hypersensitivity/immunisation reaction preferred terms (5/3 cases in the ≥ 2 months follow up subset, 13/6 cases in the whole enrolled trial population subset, 4 cases deemed severe (whole enrolled trial population), in the SOC immune system disorders).

Lymphadenopathy, nausea, and hypersensitivity are reported more often with the vaccine arm. For these items there is a reasonable possibility of a causal relation to vaccination and they are as such included in the SmPC section 4.8.

Subjects were excluded from the Phase 2/3 study if they had a history of severe adverse reaction associated with a vaccine or to any component of the BNT162b2 vaccine. The protocol did not exclude individuals with non-severe allergic reactions to other vaccines or individuals with an allergic reaction, of any severity, to medication, food or environmental allergies.

In the Phase 2/3 study 11,673 subjects had a medical history of allergic condition (n=5839 BNT162b2; n=5834 placebo), and among those two cases of allergic AEs (1 in each treatment group) occurred, which were deemed related to study treatment by the investigator. In the ~38,000 study participants with a median of 2 months of safety follow-up after Dose 2, none reported an immediate AE (occurring within 30 minutes after dosing) that was indicative of an allergic reaction to vaccine. There are incoming reports of anaphylactoid reactions from ongoing vaccination campaigns. A warning is included in the SmPC addressing the need of adequate emergency material in place at the vaccination site, which is common practice with any vaccine. Close observation for at least 15 minutes is recommended following vaccination. A second dose of the vaccine should not be given to those who have experienced anaphylaxis to the first dose.

Four cases of peripheral facial paralysis were observed in vaccine arm (facial paralysis [n=4 BNT162b2; n=0 placebo] facial paresis [n=0 BNT162b2; n=1 placebo] in total 4/1 whole enrolled trial population, however the case of paresis was not considered for this calculation). Time to onset after injection with BNT162b2 was 3, 9 and 48 days after Dose 2 and 37 days after Dose 1, which suggest a possible association with the vaccination. The two subjects with a time to onset of 3 and 9 nine days

had no previous history of Bell´s palsy, both subjects improved with prednisolone and the events were also deemed related to study intervention by the study physician. Taken together, this was considered to indicate there is a reasonable possibility of a causal relation to the vaccine, and to justify inclusion of peripheral facial paralysis (Bell´s palsy) in the SmPC 4.8 with a frequency as 'rare'.

An imbalance in PT connected to sleep disturbances was noted in the whole enrolled trial population, which was driven by 25 more cases of insomnia-related events (insomnia/sleep disorder/abnormal dreams in the BNT162b2 group versus in the placebo arm). The occurrence of insomnia may plausibly be due to e.g. local/systemic reactogenicity that may occur after vaccination. The CHMP agreed to include insomnia in section 4.8. of the SmPC.

A slight imbalance of hyperhidrosis/night sweats was noted in the whole enrolled trial population (n=26/15 BNT162b2 group versus 8/3 in the placebo arm). Hyperhidrosis as a medical term indicates a condition that differs from the sweating associated with episodes of fever. The numerical relation here is not supported by biological plausibility.

Injection site pruritus was reported in 31 subjects in the BNT162b2 group compared to 6 subjects in the placebo arm (whole enrolled trial population). These events may be plausibly associated to the injection of BNT162b2 and should therefore be included in the SmPC section 4.8.

Pain in the extremity was reported in 183 subjects in the BNT162b2 group and in 34 subjects in the placebo group (whole enrolled trial population). In addition to pain at injection site, which was commonly reported, pain in the extremity is also considered plausibly related to the vaccination and should therefore be included in the SmPC section 4.8.

Numerical imbalances in AEs for appendicitis and biliary events are observed (8/4 and 14/5 cases (whole enrolled trial population)), however these are considered not related to study treatment.

Cases of (osteo/peri) arthritis (15/15, vaccine/placebo) and psoriasis (1/1, vaccine/placebo) have been observed in the vaccine arm. These were numerically balanced in frequency between vaccine and placebo arm. Autoimmune events will be monitored post-authorisation as described in the RMP.

SAEs occurred at a low frequency in both BNT162b2 and the placebo group (0.6%, 56 cases in vaccine vs. 53 cases in placebo) in subjects with ≥2 months of follow-up post Dose 2, and a similar frequency was observed in the total study population. One SAE of lymphadenopathy and one SAE of shoulder injury were considered related to study intervention. No cases of related SAEs were reported in the adolescent group (only one case of facial bone fracture). Six events of death (2 in the BNT162b2 group and 4 in the placebo group) have been reported in the entire study population, all deemed unrelated to the vaccine.

The rate of subjects discontinuing participation in the study due to AEs was low in both study arms (0.2%/0.1%).

The subgroup of seropositive subjects is limited in size (n=545 BNT162b2; n=580 Placebo). A stratification according to serostatus for AE investigation was specifically performed in individuals with a follow up of at least one month (median Follow up 2 months) and ≥2 months. Most reported SOCs are similar to those identified in the ≥ 2 months population. AE rate in seropositive individuals was lower (22%) compared to seronegative individuals (27%) and no specific safety concern is detected in this subpopulation.

23 participants reported pregnancies in the safety database, nine of them were withdrawn from the study due to the pregnancy status. These participants will be followed up for pregnancy outcomes.

The Applicant has not provided a specific analysis of elderly individuals > 70 years included in the development program. In general, reactogenicity and AE rate were slightly lower in older compared to

younger individuals (stratified according to median age 55 years). Thus, no specific safety concern is anticipated for the elderly.

Data on immunocompromised individuals are limited, which was raised as missing information in the RMP and will be further followed up. 196 participants with stable HIV infection were included in the trial and reported AEs that were mostly reactogenicity-related with no SAEs. No specific safety concern is detected in this subpopulation.

From the safety database all the adverse reactions reported in clinical trials and post-marketing have been included in the Summary of Product Characteristics as applicable.

Assessment of paediatric data on clinical safety

The longest duration of follow-up in the 16-17 years of age group, at the time of the data cut-off, was 39 days after Dose 2. The adverse event profile for this adolescent age group did not show meaningful differences vs. the young adult group (18 to 55 years of age) in the study, albeit is numerically lower (11.6%/4.8%, vaccine/placebo).

The reactogenicity subset included a total of 8 participants in the 16 to 17 years of age group (including participants in both the BNT162b2 group and the placebo group).

Available safety data for participants 12 to 15 years of age (N=100; n=49 BNT162b2; n= 51 placebo, as recruited in the Phase 2/3 study under protocol amendment 7) show reactogenicity events (local reactions and systemic events) with no serious adverse events. The local reactogenicity profile seems comparable with the young adult population, with however a higher systemic reactogenicity as compared to young adults.

Overall, the safety of BNT162b2 in individuals 16-17 years of age is extrapolated from young adults in general.

Additional safety data needed in the context of a conditional MA

The final clinical study report for study C4591001 will be submitted no later than December 2023 and is subject to a specific obligation laid down in the MA.

2.6.11. Conclusions on the clinical safety

The safety evaluation is based on one ongoing Phase 2/3 study that at the time of data cut-off (14-Nov-20) included 43,448 subjects who received either two doses of BNT162b2 30µg (n=21 720) or placebo (n=21 728). Overall, the reported reactogenicity profile are in line with any authorised vaccine. In addition, the frequency of reported AEs and SAEs were low. The emerging safety profile is presently considered favourable. Long term safety data, interaction with other vaccines, data on use in pregnancy and other subgroups (e.g. frail subjects, or subjects with pre-existing autoimmune diseases) are missing at this stage.

The lack of long-term follow up renders the data provided non-comprehensive. Therefore, the delivery of the final C4951001 study report, including a 2-year follow up of the studied population, is classified as a specific obligation in the context of a conditional marketing authorisation.

The plan for the generation of further safety data post authorisation is described in the section below.

2.7. Risk Management Plan

Safety Specification

Summary of safety concerns

The applicant has submitted an RMP including the following summary of safety concerns:

Important identified risks	Anaphylaxis
Important potential risks	Vaccine-associated enhanced disease (VAED) including Vaccine-associated enhanced respiratory disease (VAERD)
Missing information	Use during pregnancy and while breast feeding Use in immunocompromised patients Use in frail patients with co-morbidities (e.g. chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders) Use in patients with autoimmune or inflammatory disorders Interaction with other vaccines Long term safety data

Risks considered important for inclusion of the summary of safety concerns

The review of available safety data, including post-marketing data emerging from use in the UK and US, the experience with biological products and other vaccines leads to the conclusion that anaphylaxis is an important identified risk for Comirnaty. This safety concern will be followed up via routine pharmacovigilance activities and in the planned and ongoing safety studies and reported in the monthly summary safety reports and PSURs.

Any important potential risks that may be specific to vaccination for COVID-19 (e.g. vaccine associated enhanced respiratory disease) should be taken into account. The Applicant has included VAED/VAERD as an important potential risk and will further investigate it in the ongoing pivotal study and a post-authorisation safety study.

Missing information

Since pregnant and breast-feeding women were excluded from the study, no information is available for those populations. It is agreed to include use during pregnancy and while breastfeeding as missing information in the RMP.

At the data cut-off of 14 Nov-20, 10-14 weeks safety data are available. Thus, long-term safety is included as missing information and will be characterised as part of the continuation of the pivotal clinical trial and the PASS.

Interaction with other vaccines, has not been evaluated in clinical trials and may be of interest to prescribers. As elderly individuals will be one target group for vaccination, and they often may need vaccination with other vaccines such as influenza and pneumococcus vaccines, further data is

requested. The Applicant commits to conduct a study of the co-administration of Comirnaty with inactivated quadrivalent influenza vaccine.

Data from use in frail patients with co-morbidities (e.g. chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders), is limited, and it is desirable to gather further data in these groups. Therefore, use in frail patients with co-morbidities (e.g. chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders) has been included as missing information in the RMP. Furthermore, information is limited on the use in patients with autoimmune or inflammatory disorders, as well as in immunocompromised patients. Thus, these groups are also included as missing information. Such missing information will be collected in the post-authorisation safety studies.

Risks not considered important for inclusion in the summary of safety concerns

The reactogenicity is in line with what can be expected from a vaccine, and it is considered acceptable to not include those events in the list of safety specifications.

Pharmacovigilance Plan

Routine pharmacovigilance activities

Routine pharmacovigilance activities beyond the receipt and review and submission of ADRs include:

- A **web-based AE reporting portal** will be available for vaccine providers (*e.g.* pharmacists, nurses, physicians and others who administer vaccines) and recipients, to assist with anticipated high volume of reports (based on expectations of a large target population for vaccination). The portal will capture key adverse event data in the initial interaction and will provide automated intake into the Pfizer safety database via E2B for safety review.
- **Signal detection activities** for the lifecycle of vaccines consist of individual AE assessment at case receipt, regular aggregate review of cases for trends and statistically disproportionately reported product-adverse event pairs. Aggregated and statistical reviews of data are conducted utilizing Pfizer's software interactive tools. Safety signal evaluation requires the collection, analysis and assessment of information to evaluate potential causal associations between an event and the product and includes subsequent qualitative or quantitative characterization of the relevant safety risk to determine appropriate continued pharmacovigilance and risk mitigation actions. Signal detection activities for the COVID-19 mRNA vaccine, will occur on a weekly basis. In addition, observed versus expected analyses will be conducted as appropriate as part of routine signal management activity.
- Routine signal detection activities for the COVID-19 mRNA Vaccine will include routine and specific review of AEs consistent with the AESI list provided in the RMP.
- In addition, published **literature** will be reviewed weekly for individual case reports and broader signal detection purposes.
- Regulatory authority **safety alerts monitoring**, to detect and further investigate potential signals being raised on other areas outside of EU.
- A specific adverse reaction **follow-up questionnaire** intended to capture clinical details about the nature and severity of COVID-19 illness particularly in relation to potential cases of vaccine lack of effect or VAED.

- In addition to routine 6-monthly PSUR production, monthly summary safety reports will be compiled and submitted to EMA, to support timely and continuous benefit risk evaluations during the pandemic. Minimum data to be submitted include:
  - Interval and cumulative number of reports, stratified by report type (medically confirmed/not) and by seriousness (including fatal separately);
  - Interval and cumulative number of reports, overall and by age groups and in special populations (e.g. pregnant women);
  - Interval and cumulative number of reports per HLT and SOC;
  - Summary of the designated medical events;
  - Reports per EU country;
  - Exposure data (including age-stratified);
  - Changes to reference safety information in the interval, and current CCDS;
  - Ongoing and closed signals in the interval;
  - AESI reports – numbers and relevant cases;
  - Fatal reports – numbers and relevant cases;
  - Risk/benefit considerations.
- The submission of monthly reports complements the submission of PSURs (requested initially every six months). The need and frequency of submission of the summary safety reports will be re-evaluated based on the available evidence from post-marketing after 6 months (6 submissions).
- Joint adverse event and product complaint (including available batch/lot information) trending reviews will be conducted routinely by the Applicant.

The proposed routine pharmacovigilance activities are considered appropriate for the safety profile of the product and the pandemic circumstances.

Traceability

Full traceability from manufacturing to vaccination administration site is crucial to ensure maintenance of the cold-chain as well as for pharmacovigilance purposes should assessment of a safety signal need to be performed by batch/lot.

The Applicant's proposal to ensure traceability include:

- SmPC 4.4 labelling to raise HCP awareness regarding the need to clearly record the name and batch of the vaccine to improve traceability;
- a tracking device on every vaccine shipping container that provides real-time monitoring of GPS location and temperature 24 hours per day, 7 days per week;
- vaccine carton labelling also containing a 2-D barcode which has the batch/lot and expiry embedded within
- additional tools for vaccinators to record manufacturer and lot/batch information at the time of vaccination including a Traceability and Vaccination Reminder Card and peel-off labels (stickers with brand name and lot/batch numbers), acknowledging that each Member State will decided if and how the tools will be used, in accordance with the national provisions for pharmacovigilance.

Each shipment to a vaccination site should be accompanied with a sufficient number of corresponding vaccinee traceability and vaccination reminder cards; the lot/batch numbers will be for the first batches distributed copied manually by the vaccinators, with the Applicant's commitment that by 31 January 2021 all batches shipped will be accompanied at the receipt point in the Member States by sufficient peel-off labels to facilitate the recording of brand name and lot/batch number both in the vaccinators' records and the vaccinee traceability and vaccination reminder cards, where the Member States will require it.

The Traceability and Vaccination Reminder will include:

- Space for name of vaccinee;
- Vaccine brand name and manufacturer name;
- Space for due date and actual date of first and second doses, and associated batch/lot number;
- Reminder to retain the card and bring to the appointment for the second dose of the vaccine, and keep it thereafter;
- QR code that links to additional information;
- Adverse event reporting information.

Additional pharmacovigilance activities

The Applicant proposes the following 11 studies, of which 1 global, 3 in Europe only, 2 in Europe and US, and 3 in US only; the countries where 2 studies will be conducted are not available at this time. There are 6 interventional studies (C4591001, C4591015, BNT162-01 Cohort 13, C4591018, 1 study in high risk adults and 1 study addressing co-administration with another vaccine) and 5 non-Interventional studies (4 safety and 1 effectiveness):

Study (*study short name, and title*) **Status *(planned/on-going)***	**Summary of Objectives**	**Safety concerns addressed**	**Milestone**	**Due dates**
Category 2				
C4591001 *Ongoing*	The objective of the study is to evaluate the safety, tolerability, immunogenicity and efficacy of COVID-19 mRNA vaccine An unfavorable imbalance between the vaccine and control groups in the frequency of COVID-19, in particular for severe COVID-19, may suggest the occurrence of vaccine associated enhanced disease. Surveillance is planned for 2 years following Dose 2.	Anaphylaxis Vaccine-associated enhanced disease (VAED) including vaccine-associated enhanced respiratory disease (VAERD) Use in patients with co-morbidities (C4591001 subset) Long term safety data. 			IA submission:	31-Dec-2021
Safety and immunogenicity in high risk adults *Planned*	Safety, immunogenicity over 12 months in frail elderly, immunocompromised, autoimmune and other high-risk individuals. Description of COVID-19 cases. N-antigen antibodies for detection of asymptomatic infection.	Use in frail patients with co-morbidities (e.g, chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders).	Protocol submission:	30-Jun-2021
			Final CSR submission:	31-Dec-2022
ACCESS/VAC4EU *Planned*	Assessment of occurrence of safety events of interest, including severe or atypical COVID-19 in real-world use of COVID-19 mRNA vaccine.	Anaphylaxis AESI-based safety events of interest including vaccine associated enhanced disease Use in pregnancy Use in immunocompromised patients Use in frail patients with co-morbidities (e.g, chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders) Use in patients with autoimmune or inflammatory disorders	Protocol submission:	28-Feb-2021
			Final CSR submission:	31-Jan-2024

		Long term safety data.		
Co-administration study with seasonal influenza vaccine *Planned*	Safety and immunogenicity of BNT162b2 and quadrivalent seasonal influenza vaccine when administered separately or concomitantly.	Interaction with other vaccines.	Protocol submission:	30-Sep-2021
			Final CSR submission:	31-Dec-2022

Non-Interventional Post Approval Safety Studies (4)

The Applicant proposes 4 complementary studies of real-world safety of COVID-19 mRNA vaccine that use multiple data sources and study designs.

Study C4591010 will be conducted in the EU using primary data collection to monitor a cohort of vaccinees and evaluate risk of safety events of interest reflecting the AESI list. A draft protocol C4591010 has been provided.

Additionally, Pfizer, on behalf of the Applicant, will sponsor one or more PASS using secondary electronic health records data sources in Europe based on a master surveillance protocol developed through the ACCESS project.

Two additional studies will be conducted using US data:

- 1 study using secondary data from EHR of active military and their families (C4591011),
- 1 study using secondary data from EHR of patients included in the Veterans Healthcare Administration system (C4591012).

The draft protocols for the proposed safety studies in the US (C4591011 and C4591012) have been provided.

Interventional studies (6)

The Applicant proposes 6 interventional studies, of which 2 are ongoing and 4 are planned.

- **Study C4591001** is an ongoing Phase 1/2/3, placebo-controlled, randomized, observer-blind, dose-finding study to evaluate the safety, tolerability, immunogenicity, and efficacy of SARS-CoV-2 RNA vaccine candidates against COVID-19 in healthy individuals. At the time of the data cut-off date in Study C4591001 (14 November 2020), a total of 21,720 participants received at least one dose of the candidate vaccine.
- **Study BNT162-01 Cohort 13** is an ongoing multi-site (Germany), Phase I/II, 2-part, dose escalation trial investigating the safety and immunogenicity of four prophylactic SARS-CoV-2 RNA vaccines against COVID-19 using different dosing regimens in 30 immunocompromised adults.
- **Study C4591015** is a planned clinical study to assess safety and immunogenicity in pregnant women who receive COVID 19 mRNA vaccine.
- **Study C4591018** is a planned study of BNT162b2 in 100 adults receiving a stable dose of immunomodulators for the treatment of stable rheumatoid arthritis (RA), in two cohorts (50 tofacitinib, 50 TNF inhibitors). Subjects will be studied for safety, immunogenicity by neutralizing antibody titer, and evidence of asymptomatic infection by N-antigen antibodies.

- A planned **Phase II safety and immunogenicity study** (Safety and immunogenicity in high risk adults) in up to 150 immunocompromised adults (with a range of primary immunocompromising conditions and/or receiving immunocompromising treatments.
- **Co-administration study with seasonal influenza vaccine** study investigating the safety and immunogenicity of Comirnaty and quadrivalent seasonal influenza vaccine when administered separately or concomitantly.

Non-Interventional PASS in Pregnancy

The Applicant's proposed strategy to assess vaccination during pregnancy will be implemented in 2 stages. It is anticipated that initial use in pregnancy will be very limited; therefore, initially this information will derive from the 4 of the real-world safety studies (C4591010, C4591011, and ACCESS/VAC4EU), described in the preceding section. Study C4591012 is focused on patients in the Veterans Health Administration system and is not expected to capture many pregnancies given the demographics of the source population.

The findings from studies' interim analysis (where planned) will inform a strategy to assess pregnancy outcomes as vaccination in pregnancy expands. The Applicant will consider established EU pregnancy research recommendations such as CONSIGN (COVID-19 infectiOn aNd medicineS In pregnancy) when developing any pregnancy related study objectives. The applicant's commitment and considerations are noted to evaluate pregnancy outcomes in a PASS using established EU pregnancy research recommendations such as CONSIGN (COVID-19 infectiOn aNd medicineS In pregnancy) when developing any pregnancy related study objectives. Further feasibility analyses are awaited with RMP updates post-approval.

Non-Interventional Post-Approval Effectiveness study (1)

The Applicant will conduct at least one non-interventional study (test negative design) of individuals presenting to the hospital or emergency room with symptoms of potential COVID-19 illness in a real-world setting (C4591014). The effectiveness of COVID-19 mRNA vaccine will be estimated against laboratory confirmed COVID 19 illness requiring admission to the Emergency Department (ED) or hospital where SARS-CoV-2 is identified. These studies will allow to determine the effectiveness of Pfizer's vaccine in a real-world setting and against severe disease, and in specific racial, ethnic, and age groups. The studies proposed below are under evaluation as potential commitments; studies are presented by geographical area (US and EU).

Overall conclusions on the Pharmacovigilance Plan

The proposed post-authorisation pharmacovigilance development plan is sufficient to identify and characterise the risks of the product.

Routine pharmacovigilance remains sufficient to monitor the effectiveness of the risk minimisation measures.

Plans for post-authorisation efficacy studies

None proposed.

Risk minimisation measures

Routine Risk Minimisation Measures

Potential Medication Errors

The Applicant included a discussion on potential medication errors which is endorsed:

Large scale public health approaches for mass vaccination may represent changes to standard vaccine treatment process, thereby potentially introducing the risk of medication errors related to: reconstitution and administration, vaccination scheme, storage conditions, errors associated with a multi-dose vial, and once other COVID-19 vaccines are available, confusion with other COVID-19 vaccines. These potential medication errors are mitigated through the information in the SmPC and further materials for healthcare providers which will be made available to the Member States to be integrated in the national campaign for communication, as needed.

- SmPC (section 6.6) contains instructions for reconstitution and administration, vaccination scheme, and storage conditions of the COVID-19 mRNA vaccine.
- A poster with step-by-step instruction for vaccine storage, dose planning and preparation, and administration is available, which can be conspicuously displayed in settings where vaccine is to be administered for ongoing reference.
- Brochures for safe handling of the vaccine and dry ice will accompany vaccine shipments.
- Medical information call centres will be available for healthcare providers to obtain information on use of the vaccine.
- Traceability and Vaccination Reminder card will be provided with the pre-printed manufacturer name, dates of vaccination, batch/lot as a mitigation effort for potential confusion between vaccines.
- Peel-off labels with lot/batch number

These available resources will inform healthcare providers on the proper preparation and administration of the vaccine and reduce the potential for medication errors in the context of a mass vaccination campaign. Additionally, the patient information leaflet and, in those MSs where applicable, a Traceability and Vaccination Reminder card informs patients of the vaccine received so that a series is completed with the same product.

Summary of additional risk minimisation measures

None proposed.

The Applicant stated that Routine risk minimisation activities are sufficient to manage the safety concerns of the medicinal product. This is acceptable.

Safety Concern	**Risk Minimisation Measures**	**Pharmacovigilance Activities**
Important Identified Risks		
Anaphylaxis	Routine risk minimisation measures: SmPC sections 4.4. and 4.8. Additional risk minimisation measures: None.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: DCA is intended to facilitate the capture of clinical details about potential anaphylactic reactions in individuals who have received the COVID-19 mRNA vaccine Additional pharmacovigilance activities: Studies (Final CSR Due Date): • C4591001 (31-Aug-2023) • C4591010 (31-Mar-2024) • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • ACCESS/VAC4EU (31-Jan-2024).
Important Potential Risks		
Vaccine-associated enhanced disease (VAED) including Vaccine-associated enhanced respiratory disease (VAERD)	Routine risk minimisation measures: None. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: DCA is intended to facilitate the capture of clinical details about the nature and severity of COVID-19 illness in individuals who have received the COVID-19 mRNA vaccine and is anticipated to provide insight into potential cases of vaccine lack of effect or VAED Additional pharmacovigilance activities: Studies (Final CSR Due Date) • C4591001 (31-Aug-2023) • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • ACCESS/VAC4EU (31-Jan-2024).
Missing information		
Use in pregnancy and while breast feeding	Routine risk minimisation measures: SmPC section 4.6; PL section 2.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None.

Safety Concern	**Risk Minimisation Measures**	**Pharmacovigilance Activities**
	Additional risk minimisation measures: No risk minimisation measures.	Additional pharmacovigilance activities: Studies (Final CSR Due Date) • C4591010 (31-Mar-2024) • C4591011 (31-Dec-2023) • C4591015 (30-Apr-2023) • ACCESS/VAC4EU (31-Jan-2024).
Use in immunocompromised patients	Routine risk minimisation measures: SmPC sections 4.4 and 5.1. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None. Additional pharmacovigilance activities: Studies (Final CSR or IA Due Date) • BNT162-01 Cohort 13 (IA: 30-Sep-2021, CSR: 31-Dec-2022) • C4591018 (IA: 31-Dec-2021) • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • ACCESS/VAC4EU (31-Jan-2024).
Use in frail patients with co-morbidities (e.g. chronic obstructive pulmonary disease (COPD), diabetes, chronic neurological disease, cardiovascular disorders)	Routine risk minimisation measures: SmPC section 5.1. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None. Additional pharmacovigilance activities: Studies (Final CSR Due Date submission) • C4591001 subset (31-Aug-2023) • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • ACCESS/VAC4EU (31-Jan-2024) • Safety and immunogenicity in high risk adults (31-Dec-2022).

Safety Concern	**Risk Minimisation Measures**	**Pharmacovigilance Activities**
Use in patients with autoimmune or inflammatory disorders	Routine risk minimisation measures: None. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None. Additional pharmacovigilance activities: • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • C4591018 (31-Dec-2021) • ACCESS/VAC4EU (31-Jan-2024).
Interaction with other vaccines	Routine risk minimisation measures: SmPC section 4.5. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None. Additional pharmacovigilance activities: • Co-administration study with seasonal influenza vaccine (31-Dec-2022).
Long term safety data	Routine risk minimisation measures: None. Additional risk minimisation measures: No risk minimisation measures.	Routine pharmacovigilance activities beyond adverse reactions reporting and signal detection: None. Additional pharmacovigilance activities: Studies (Final CSR Due Date or IA CSR submission) • C4591001 (31-Aug-2023) • C4591010 (31-Mar-2024) • C4591011 (31-Dec-2023) • C4591012 (31-Dec-2023) • ACCESS/VAC4EU (31-Jan-2024).

Overall conclusions on risk minimisation measures

The proposed risk minimisation measures are sufficient to minimise the risks of the product in the proposed indication(s).

Summary of the risk management plan

The public summary of the RMP is acceptable.

Conclusion on the RMP

The CHMP and PRAC considered that the risk management plan **version 1.0** is acceptable.

2.8. Pharmacovigilance

Pharmacovigilance system

The CHMP considered that the pharmacovigilance system summary submitted by the applicant fulfils the requirements of Article 8(3) of Directive 2001/83/EC.

Periodic Safety Update Reports submission requirements

The requirements for submission of periodic safety update reports for this medicinal product are set out in the Annex II, Section C of the CHMP Opinion. Furthermore, During the duration of the COVID-19 pandemic situation, the MAH shall submit summary safety reports submitted to EMA, including spontaneously reported data and data from compassionate use and expanded access programs. The applicant did not request alignment of the PSUR cycle with the international birth date (IBD). The new EURD list entry will therefore use the EBD to determine the forthcoming Data Lock Points.

2.9. Product information

2.9.1. User consultation

The results of the user consultation with target patient groups on the package leaflet submitted by the applicant show that the package leaflet meets the criteria for readability as set out in the *Guideline on the readability of the label and package leaflet of medicinal products for human use.*

2.9.2. Labelling exemptions

The following exemptions from labelling and serialization requirements have been granted on the basis of article 63.3 of Directive 2001/83/EC. In addition, the derogations granted should be seen in the context of the flexibilities described in the *Questions and Answers on labelling flexibilities for COVID-19 vaccines* (EMA/689080/2020 rev.1, from 16 December 2020)[5] document which aims at facilitating the preparedness work of COVID-19 vaccine developers and the associated logistics of early printing packaging activities. The ultimate goal is to facilitate the large scale and rapid deployment of COVID-19 vaccines for EU citizens within the existing legal framework.

Labelling exemptions

US packaging specific derogations (valid for December '20 and January '21)

All EU Members States (MSs), as well as Norway and Iceland, have agreed to grant a temporary

[5] Available at https://www.ema.europa.eu/en/documents/other/questions-answers-labelling-flexibilities-covid19-vaccines_en.pdf, last consulted on 21 December 2021.

exemption to allow the placing in the EU market of the US packaging, under the following conditions:

a. The validity is only temporary and the MAH shall switch to the EU labelling requirements by February '21;

b. The US pack will have included a Quick Response (QR) code which the vaccine recipient could scan and gain access to the package leaflet (PL) in his/her national language;

c. The MAH shall supply a separate printed PL in the national language(s) of those MSs that require so, i.e. Belgium, Bulgaria, Croatia, Czech Republic, France and Greece. All other MSs, that have granted a temporary exemption for an EN only PL, will receive 5 printed copies of the EN PL with each shipment of the vaccine.

EU packaging specific derogations (from February '21 onwards)

a. Outer and immediate labelling will be provided in English only.

The MAH shall provide outer and immediate labelling in all EU languages by 2nd Q 2022. This exemption is justified on the deep-frozen storage/shipping requirements and the necessity to label batches ahead of time. Production of different vaccine packs in different languages will significantly reduce the supply chain efficiency. The multiple changes on packaging lines will result in significant time and capacity losses and would slow down the rapid deployment of COVID-19 vaccines. Moreover, English only labelling will better help to manage a shortage situation in one country by using immediately the supply from another country.

b. A printed package leaflet will be provided in the national language(s) for those MSs that require so, i.e. Belgium, Bulgaria, Croatia, Czech Republic, France and Greece. All other MSs, that have granted a temporary exemption for an EN only PL, will receive 5 printed copies of the EN PL with each shipment of the vaccine. In addition, a QR code printed on the outer label and the PL will provide access to the package leaflet in the national language(s).

The MAH shall provide a printed package leaflet in all EU languages by 2nd Q 2022.

The MAH shall engage with the National Competent Authorities (other than the 6 mentioned above) to discuss and speed up the provision of PLs in the respective national language(s) of the MSs concerned. The MAH shall also contact MSs directly to agree on the exact numbers of PLs to be distributed, again in line with the published Q&A on labelling flexibilities.

c. The Blue Box will be omitted for the initial batches. The MAH shall provide the Blue Box via a QR code at a later stage following agreement on exact timing of implementation with the National Competent Authorities in each MS.

d. The inclusion of the EU Marketing Authorisation number in the labelling will be implemented with the switch from US packaging to EU compliant packs in February 2021.

Exemption from the obligation of serialisation

US packaging specific derogations (valid for December '20 and January '21)

a. It is acceptable that the US pack will be placed in the EU market without serialisation according to the EU FMD requirements. Only the Global Trade Item Number (GTIN) will be common for US & EU and this will be printed on the US pack.

EU packaging specific derogations (from February until March '21)

- All EU Member States have accepted a temporary derogation from serialisation for the EU pack from February until the end of March 2021.

- The MAH shall provide two progress reports on the serialisation: a first by 1st of February '21 and a second by 1st of March '21 referring to details on the progress achieved in terms of ensuring compliance, e.g. proof of acquiring the relevant equipment, the date for the validation, the proof of contract to connect to the European Medicines Verification Organisation.

- The MAH shall provide additional mitigating measures, e.g. immediate reporting of any stolen product during the period of exemption, reporting of any counterfeit or falsified vaccine in the EU or third countries in the legal supply or internet, reconciliation of product distributed and used in the respective territory.

2.9.3. Quick Response (QR) code

A request to include a QR code in the labelling and the package leaflet for the purpose of providing information to Healthcare Professionals and vaccine recipients has been submitted by the applicant and has been found acceptable.

The following elements have been agreed to be provided through a QR code:

- The Summary of Product Characteristics
- The Package Leaflet
- Safe Handling Guidelines for Dry Ice
- Shipping and Handling Guidelines Brochure
- Preparation and Administration Video
- Storage and Handling Video
- Returning the Thermal Shipping Container video
- How to prepare and Administer Poster
- Traceability and vaccination reminder card
- Returning the thermal Shipping Container brochure
- Dry Ice Replenishment Brochure
- Link to Adverse Event Reaction Reporting

2.9.4. Additional monitoring

Pursuant to Article 23(1) of Regulation (EC) No 726/2004, Comirnaty (COVID-19 mRNA vaccine (nucleoside-modified)) is included in the additional monitoring list as it contains a new active substance which, on 1 January 2011, was not contained in any medicinal product authorised in the EU and it is approved under a conditional marketing authorisation.

Therefore, the summary of product characteristics and the package leaflet includes a statement that this medicinal product is subject to additional monitoring and that this will allow quick identification of new safety information. The statement is preceded by an inverted equilateral black triangle.

3. Benefit-Risk Balance

3.1. Therapeutic Context

3.1.1. Disease or condition

COVID-19 is an infectious disease caused by a newly discovered coronavirus, SARS-CoV-2, which appeared in the Wuhan province in China in 2019 and has spread world-wide during 2020 ever since, causing WHO to declare a pandemic on 11 March 2020. The virus infects primarily the airways and causes a broad spectrum of respiratory infections from asymptomatic infection to Severe Acute Respiratory Syndrome (SARS). The pandemic is ongoing despite unprecedented efforts to control the outbreak. According to ECDC histologic findings from the lungs include diffuse alveolar damage similar to lung injury caused by other respiratory viruses, such as MERS-CoV and influenza virus. A distinctive characteristic of SARS-CoV-2 infection is vascular damage, with severe endothelial injury, widespread thrombosis, microangiopathy and angiogenesis.

As of 1 December 2020, there have been >63 million globally confirmed COVID-19 cases and >1.4 million deaths, with 191 countries/regions affected.

At the time of this marketing application submission, confirmed cases and mortality continue to rise globally. The ongoing pandemic remains a significant challenge to public health and economic stability worldwide.

Comirnaty is intended for active immunisation against SARS-CoV-2, thereby preventing COVID-19.

3.1.2. Available therapies and unmet medical need

There is currently no approved vaccine in the EU available to prevent COVID-19. Several development programs are ongoing globally and currently other applications are under evaluation by regulatory authorities worldwide. There is a very high global demand for vaccines to help contain the pandemic and decrease morbidity and mortality in at risk groups.

3.1.3. Main clinical studies

The clinical development consists of one FIH phase 1 study (BNT162-01) in younger and older adults (18-55 years and 56-85 years) comparing 4 vaccine candidates, and one pivotal clinical study, C4591001 (or BNT162-02).

The pivotal study is a phase 1/2/3 placebo-controlled, randomised, observer-blind, dose finding, multicentre study performed in the US (start date 4 May 2020), Argentina, Brazil, Turkey, Germany, and South Africa, to evaluate the safety, immunogenicity and efficacy of a SARS-CoV-2 mRNA vaccine candidate against COVID-19 in healthy adults. The phase 1 part of the study was designed for dose evaluation of 2 vaccines: BNT162b1 and BNT162b2 in younger (18-55 years) and older (65-85 years) adults. The Phase 2 part was designed to confirm safety and immunogenicity of the selected vaccine, BNT162b2, in the first 360 subjects enrolled in the Phase 2/3 part of the study.

The Phase 2/3 part of the study was designed to enrol up to 43,998 subjects (randomised 1:1 to BNT162b2 or placebo) to receive BNT162b2 at the dose of 30 µg, given as 2 IM injections 21 day apart (within 19 to 42 days), for an efficacy assessment in addition to safety and exploratory immunogenicity assessments.

The primary endpoint was symptomatic COVID-19 incidence per 1000 person-years of follow-up based on centrally or locally confirmed nucleic acid amplification test (NAAT) in subjects without serological or virological evidence of SARS-CoV-2 infection before and during vaccination regimen (cases confirmed ≥7 days after Dose 2), and in subjects with and without evidence of SARS-CoV-2 infection before and during vaccination regimen. The study was event-driven, i.e. the final efficacy analysis was to be triggered by 162 cases; in practice 170 cases were reached.

3.2. Favourable effects

The overall vaccine efficacy against symptomatic laboratory confirmed COVID-19 from 7 days after dose 2 was 95.0% (95% CI 90.0, 97.9) in subjects ≥16 years of age without prior evidence of SARS-CoV2 infection and 94.6% (95% CI 89.6, 97.6) in all subjects regardless of prior evidence of SARS-CoV-2 infection (primary endpoint). This outcome met the pre-specified success criteria.

Vaccine efficacy after dose 1 to before dose 2 was 52.4% (95% CI 29.5, 68.4). Vaccine efficacy from 10 days after dose 1 to before dose 2 was estimated to be 86.7% (95% CI 68.6, 95).

The efficacy analyses in the all-available efficacy population (including participants who had protocol violations), showed consistent results with those in the primary analysis population. The efficacy analyses using CDC defined symptoms to identify a COVID-19 case gave similar efficacy results as the primary endpoints.

The VE in each demographic subgroup analysed, as defined by age (including subjects >65 years), sex, race, ethnicity, and country and in individuals with comorbidities including obesity, diabetes, hypertension and cardiopulmonary diseases was >90%. In the obese population, VE was 95.4% (CI 95% 86.0%, 99.1%).

VE among 65-74-year-olds was 92.9% (CI95% 53.1%, 99.8%). VE among >75-year-olds was 100% (CI95% -13.1%, 100.0) with 0 cases in the vaccine group and 5 cases in the placebo group. VE among >65 years and at risk of severe COVID-19 was 91.7% (95% 44.2%, 99.8%).

Secondary efficacy analyses suggested benefit of the vaccine in preventing severe COVID-19, but the number of cases after second dose was very low, 1 case in the vaccine group and 4 cases in placebo group. Counting cases from after dose 1, there were 1 case in the vaccine group and 9 cases in the placebo group.

Phase 1 and phase 2 immunogenicity data from both the pivotal study C4591001 and supportive study BNT162-01 have shown robust humoral responses after vaccination with 2 doses of BNT162b2 at 30 µg in both younger (18-55 years) and older adults (age groups 56-85 years and 65-85 years), and both in terms of neutralising antibodies and IgG-antigen binding antibodies. The second dose given 21 days post-dose 1 induced a marked boosting effect in both younger and older adults. Responses were generally faster and higher in younger adults than in older adults. The levels of neutralizing antibodies titres were moderate 21 days after dose 1. The peak of neutralizing antibodies titres was reached 14 days post-dose 2 in older adults versus 7 days post-dose 2 in younger adults. Immune responses were maintained up to 1-month post-dose 2 in both age groups based on available data.

Study BNT162-01 provides evidence for T cell-mediated immune response, with antigen-induced IFNγ expression demonstrating a Th1 CD4+ and CD8+ phenotype following the second dose of vaccine. For the 30 µg dose cohort vaccinated with BNT162b2, CD4 and CD8 cytokine responses showed the same intensity in adults and older adults.

The immunogenicity results are only considered supportive at this stage, as no correlate of protection has been established. The immune responses support the need for two doses, as neutralising antibody

levels increased substantially following the second dose compared to the first dose. Cell mediated immune responses were demonstrated in very few subjects in phase 1 but confirm a Th1 dominated cytokine pattern.

3.3. Uncertainties and limitations about favourable effects

Based on the available limited data, no reliable conclusion on the efficacy of the vaccine against severe COVID-19 can be drawn from 7 days after the second dose (secondary endpoint). The estimated efficacy against severe COVID-19 occurring at least 7 days after dose 2 was 66.4%, with a large and negative lower bound CI (95% CI: -124.8%; 96.3%). Only a limited number of events occurred at the cut-off date of analysis (1 and 4 cases in the vaccine and placebo groups respectively). The posterior probability for the true vaccine efficacy ≥ 30% (74.29%) did not meet the pre-specified success criterion. Consequently, the efficacy against the severe disease across subgroups, notably certain populations at high-risk of severe COVID-19 cannot be estimated (elderly and subjects with comorbidities).

Efficacy against asymptomatic infection is not available but, notwithstanding all the limitations, will be assessed through seroconversion of N-binding antibodies in BNT162b2 and placebo recipients who did not experience COVID-19.

The pivotal study was not designed to assess the effect of the vaccine against transmission of SARS-CoV-2 from subjects who would be infected after vaccination. The efficacy of the vaccine in preventing SARS-CoV-2 shedding and transmission, in particular from individuals with asymptomatic infection, can only be evaluated post-authorisation in epidemiological or specific clinical studies.

Duration of protection has currently been followed up for approximately 100 days after dose 1. Data on longer term protection are anticipated to the extent that the ongoing phase 3 study can continue as planned with a placebo group. The assessment of efficacy over a period of at least 6 months is expected to determine the need and the appropriate time of a booster dose.

There seems to be at least a partial onset of protection after the first dose, but this remains unconfirmed at this stage.

There are very limited or no data in immunocompromised subjects and in pregnant women. Efficacy in subjects aged 16-17 years is extrapolated from young adults as no cases of disease were reported in this small group at this stage.

Available data do not suffice to establish efficacy in subjects seropositive for SARS-CoV-2 at baseline, and subjects with a known history of COVID-19. However, efficacy is anticipated in this group; to the extent that they are not naturally protected against re-infection, which is presently incompletely characterised.

3.4. Unfavourable effects

The safety of Comirnaty was evaluated in participants 16 years of age and older in 2 clinical studies (BNT162-01 and C4591001) that included 21,744 participants that have received at least one dose of Comirnaty.

In Study C4591001, a total of 21,720 participants 16 years of age or older received at least 1 dose of Comirnaty and a total of 21,728 participants 16 years of age or older received placebo (including 138 and 145 adolescents 16 and 17 years of age in the vaccine and placebo groups, respectively). A total of 20,519 participants 16 years of age or older received 2 doses of Comirnaty.

At the time of the analysis of Study C4591001, a total of 19,067 (9,531 Comirnaty and 9,536 placebo) participants 16 years of age or older were evaluated for safety for at least 2 months after the second dose of Comirnaty. This included a total of 10,727 (5,350 Comirnaty and 5,377 placebo) participants 16 to 55 years of age and a total of 8,340 (4,181 Comirnaty and 4,159 placebo) participants 56 years and older. Reactogenicity was evaluated in a subset of 8183 subjects (n=4093 vaccinated; n=4090 placebo) up to 7 days after each dose.

Regarding reactogenicity, the most frequent adverse reactions in participants 16 years of age and older were injection site pain (> 80%), fatigue (> 60%), headache (> 50%), myalgia and chills (> 30%), arthralgia (> 20%), pyrexia and injection site swelling (> 10%). All reactions were usually mild or moderate in intensity and resolved within a few days after vaccination. A slightly lower frequency of reactogenicity events was associated with greater age. The frequency of headache, fatigue and fever was higher after Dose 2 in both age groups.

Regarding AEs, at least one AE was reported in 21% of the vaccinated subjects and in 13% of the placebo arm. The frequency of severe AEs was low (<1%) in both study arms. The most frequently reported SOC were "General disorders and administration site conditions (11.9% vs 2.9%)", "musculoskeletal reactions" (5.5% vs 2.1%), and "nervous system disorders" (4.2% vs 2.1%). PTs comprised mainly of vaccine typical reactions such as injection site pain, headache, fever, fatigue, malaise as well as myalgia and arthralgia.

For subjects with a follow-up of ≥2 months, SAE were reported at a low frequency (0.5-0.6%) in both the vaccine and the placebo group, with no clinically meaningful differences by age, baseline serostatus, ethnicity, race or sex. Lymphadenopathy and nausea were reported to occur more often in the vaccine group compared to the placebo group in the whole enrolled trial population (respectively 0.4% and 0.6% higher rate than placebo). Numerical imbalances in reporting were observed for insomnia, injection site pruritus and pain in extremity. Since these are supported by a biologically plausible relation to vaccination, these AEs are reflected in the SmPC.

Acute peripheral paralysis was reported in 4 vs. 0 cases (vaccine vs placebo) in the whole study population, of which 2 cases were deemed related to study treatment (see section 2.6.10). For acute peripheral paralysis, there is a reasonable possibility of a causal relation to vaccination and should therefore be included in the SmPC.

In the ~38,000 study participants with a median of 2 months of safety follow-up after Dose 2, none reported an immediate AE (occurring within 30 minutes after dosing) that was indicative of an allergic reaction to vaccine. Three reports of anaphylaxis were identified during vaccination campaigns by the time this report was written.

Few cases of hypersensitivity/immunisation reaction events have been observed with the vaccine (13 vs 6 cases) in the whole study population. Hypersensitivity should be annotated in the SmPC, section 4.8.

3.5. Uncertainties and limitations about unfavourable effects

Long term safety data is not available at this stage, however the Phase 2/3 study will follow the included subjects up to 2 years post vaccination, so these data are expected post-authorisation.

AEs were slightly lower in subjects seropositive to SARS-CoV-2 at baseline (22% vs. 27% in seronegatives), however the number of such subjects was limited (vaccinated n=558; placebo n=590).

Data on immunocompromised individuals is limited, as only 196 participants with stable HIV infection were included in the study. No specific safety concern was detected.

Data from exposure during pregnancy is very limited. Up to the cut-off date 23 pregnancies have been reported in the Phase 2/3 trial and will be followed up for outcome.

Multiple long-term pharmacoepidemiology safety studies are planned to be conducted in order to confirm the safety profile in the already studied population as well as in a broader population including pregnant, immunocompromised and very elderly subjects.

There is no data available on interaction with other vaccines given in co-administration.

In the Phase 2/3 study, the total number of included subjects aged 16-17 years was smaller compared to other age groups (n=138 BNT162b; n=145 placebo), however no safety concerns were identified.

Uncertainties remain regarding causality association of acute peripheral paralysis to vaccination due to the limited number of cases, which are consistent with background rates. Nevertheless, facial paralysis will be included as an adverse event of special interest (AESI) for pharmacovigilance monitoring and in the active surveillance study protocols.

While apart from facial paralysis, whose aetiology is currently unknown, no possible autoimmune adverse events where identified as causally related to vaccination, rare events of this nature cannot be excluded based on the size of the available data set.

There is a theoretical risk, based on non-clinical data with MERS and SARS vaccines, of vaccine-associated enhanced disease (VAED) including vaccine-associated enhanced respiratory disease (VAERD), however no cases were identified in clinical studies with COVID-19 vaccines, including Comirnaty, and the characterisation of the immune response does not indicate a risk profile in this regard (Th1 skewed).

This vaccine contains two new components (cationic lipid ALC-0315 and PEGylated liquid ALC-0159) in the LNP, for which there is limited experience. Some uncertainties remain regarding the ALC-0315 long half-life. Regarding PEG related toxicity which is known to depend on the dose, dose frequency, duration of treatment and molecular weight of the PEG protein, immunogenicity is not expected to be an issue due to the low molecular weight of this PEG (<2KDa). The scientific data available at this stage do not raise noticeable concerns regarding immunogenicity or immunotoxicity of the PEG, but current evidence is not definitive.

3.6. Effects Table

Table 20 Effects Table for Comirnaty intended for active immunisation to prevent COVID-19 caused by against SARS-CoV-2 in individuals 16 years of age and older (data cut-off: 14 Nov 2020)

Effect	Short Description	Unit	BNT162b2 (30 µg)	Placebo	Uncertainties / Strength of evidence	References
Favourable Effects						
Vaccine efficacy	First COVID-19 occurrence from 7	**% (95% CI)**	**95.0** (90.0, 97.9)			

Effect	Short Description	Unit	BNT162b2 (30 µg)	Placebo	Uncertainties / Strength of evidence	References
	days after Dose 2, without prior SARS-COV-2, **overall**	**Cases/** Number of subjects at risk for the endpoint	**8/** 17411	**162/** 17511	Robust data with similar efficacy confirmed in all age sub-groups (16-64YOA, >65YOA, 65-74YOA, >75YOA)	Evaluable efficacy population (7 days post dose 2) - Study C495100
		% **(95% CI)**	**94.7** (66.7, 99.9)			
	Patients aged ≥65	**Cases/** Number of subjects at risk for the endpoint	**1**/3848	**19**/3880

3.7. Benefit-risk assessment and discussion

3.7.1. Importance of favourable and unfavourable effects

Overall, substantial efficacy in preventing symptomatic COVID-19 infection has been demonstrated, as well as an acceptable safety profile in a large phase 3 study. Uncertainties relate to the

characterization of active substance and finished product. Given the comparable immunogenicity from 10 to 30µg doses, an impact on efficacy of the acceptance of somewhat lower levels of intact mRNA in the commercial product is not considered likely. Furthermore, based on low levels and biological plausibility, an impact of mRNA impurities on safety is deemed unlikely (see section 3.7.3).

Due to the limited extent of safety follow-up, the delivery of final data from the full 2-year follow up in the pivotal clinical trial are considered important to confirm the current knowledge.

With regards to the balance of efficacy and safety benefits and risks, it is overwhelmingly positive for subjects at risk of severe COVID-19, including the elderly and those with comorbid conditions, which are known to increase the risk of complication and death due to infection.

Uncertainties concerning the pharmaceutical characterization of the commercial product are compatible with a positive benefit/risk balance. This pertains not only to adults but, by extrapolation, to individuals 16-17 years of age.

Data are limited in individuals seropositive against SARS-CoV-2 at baseline. Available data however do not indicate any specific safety concerns, and efficacy is anticipated also in this subset.

There are no data on use in pregnant women, but a protective effect is anticipated. In the light of the reassuring data from the DART study, noting that pregnancy as such is a risk factor for severe COVID-19, and that pregnant women may additionally belong to other risk groups, vaccination may be considered on a case by case basis.

Based on biological plausibility no risk in breastfeeding is anticipated.

While there was no indication of an excess risk of severe allergic reactions such as anaphylaxis in the clinical study program, three post marketing cases, of which 2 in patients carrying adrenaline pens and one in a person with no known history of allergies, have been reported during vaccination campaigns, and all resolved with standard treatment. Hypersensitivity to the active substance or to any of the excipients is a contraindication. However, there is presently no substantial evidence of a negative benefit/risk balance in a subject with severe allergy to substances absent in the vaccine. For all subjects, the vaccine should be administered in settings where resuscitation facilities are available, as specified in the SmPC and in line with other vaccines. A second dose of the vaccine should not be given to those who have experienced anaphylaxis to the first dose.

There are no efficacy data in immunocompromised individuals. Such patients may not be protected as well as immunocompetent individuals by vaccination. While there are limited safety data too in the immunocompromised subjects (a broad and disparate category), no particular safety issues are anticipated, and the benefit/risk balance of vaccination of such subjects is deemed positive, also in light of the underlying excess risk of COVID-19.

Studies to monitor potential safety concerns (autoimmune disorders, VAED) are planned.

3.7.2. Balance of benefits and risks

Overall, the available data are supportive of a positive B/R in the proposed indication.

3.7.3. Additional considerations on the benefit-risk balance

Given the emergency situation, it is considered that the identified uncertainties can be addressed post-authorisation in the context of a conditional MA, including further characterisation of the active substance and finished product, the continuation of the pivotal study as long as possible, and post-approval effectiveness studies and routine disease surveillance.

Conditional marketing authorisation

Efficacy, safety and immunogenicity was demonstrated using clinical batches of vaccine (Process 1). The commercial batches are produced using a different process (Process 2), and the comparability of these processes relies on demonstration of comparable biological, chemical and physical characteristics of the active substance and finished product.

The characterisation and control of active substance and finished product are limited in relation to critical quality attributes and impurities.

Data demonstrates the presence of truncated/modified forms of mRNA at somewhat higher levels in the batches manufactured with the commercial process as compared to material used in clinical trials. These forms are not sufficiently characterised, and although the limited data provided for protein expression does not fully address uncertainties relating to the risk of translating proteins/peptides other than the intended spike protein, the amount of any such proteins, is expected to be too low to elicit an immune response of biological relevance.

Indeed, considering the low dose of mRNA (30 µg), the impurities are not considered a safety issue based on general toxicological principles. However, when present in the cell it cannot be excluded that different proteins than the intact full-length spike will be expressed. The risk of unwanted immunological events is considered low based on the following observations and considerations:

- Such impurities were present in the vaccine used in the Phase 3 clinical trials with an acceptable safety profile. Although the lack of characterisation hinders a full comparability evaluation there is no indication that there would be important qualitative differences in the nature of these impurities.
- The high levels of these impurities reflect the instability of RNA resulting in generation of RNA fragments both in the transcription step and thereafter. Based on electrophoretic data it appears that there is a diverse set of fragments. Although not confirmed, it is unlikely that these RNA molecules to a large extent would be mRNA molecules with intact 5'-cap and 3'-polyA able to be translated into a specific protein or peptide.
- The level of any individual fragment of mRNA species would anyway be magnitudes lower than the level of the intact mRNA and this would be mirrored by the level of protein expression. The spike protein is a highly immunogenic protein and immunodominance would also ascertain that the immune response to the truncated proteins would be non-significant.

Also, lipid related impurities were observed in recently produced finished product batches. Based on the low dose (30 µg mRNA) it is considered that the amounts of these impurities are too low to be of toxicological significance.

Regarding the proposed control strategy for active substance and finished product, questions were raised both with regard to the suitability of the test methods used and the acceptance criteria for some tests.

Considering the above and the current public health emergency, the characterisation of the active substance and finished product are considered acceptable, and the proposed specifications for RNA integrity and 5'-Cap are considered to be scientifically justified and acceptable. Nevertheless, additional data to complete the characterisation of the active substance and finished product, and considering clinical experience, are considered important to confirm the adequacy of these specifications, and these data should be provided post-approval as specific obligations to the MA.

Therefore, the CHMP considers that the product fulfils the requirements for a conditional marketing authorisation:

- The benefit-risk balance is positive, as discussed.
- It is likely that the applicant will be able to provide comprehensive data.

Studies are underway to complete the characterisation of the active substance and finished product, and additional clinical data from batches currently in use in ongoing clinical studies, are considered important to confirm the clinical qualification of these specifications. Based upon the applicant's justification and commitment, detailed plans have been agreed with the applicant and reflected in the quality part of this assessment regarding data to be generated and submitted with interim milestones for assessment by the CHMP in order to complete all proposed specific obligations. Based on the Applicant's plans and documentation, it is expected that data to fulfil all quality SOs will be submitted gradually between March and July 2021.
Furthermore, the applicant will continue the ongoing pivotal Phase 3 randomized, placebo-controlled, observer-blind study C4591001 to obtain 2-year long-term data and to ensure sufficient follow-up in order to confirm the efficacy and safety of Comirnaty.

- Unmet medical needs will be addressed

There is no approved or widely available COVID-19 vaccine, and COVID-19 remains associated with substantial morbidity and mortality. While care for patients who have COVID-19 has improved over time and with clinical experience, no medications to cure COVID-19 are available and there remains an urgent need for a prophylactic vaccine during the ongoing pandemic.

- The benefits to public health of the immediate availability outweigh the risks inherent in the fact that additional data are still required.

Convincing efficacy evidence including the elderly and those with comorbid conditions has been provided and long-term effectiveness and safety data will be provided post-authorisation. Taking all this into account, it would not be considered appropriate to withhold a highly beneficial vaccine considering the severity of COVID-19 disease and the current global pandemic situation, since the demonstrated benefits in the current emergency setting clearly outweigh the uncertainties of the available data as outlined above.

3.8. Conclusions

The overall benefit/risk balance of Comirnaty is positive.

As available data are non-comprehensive, granting of a conditional marketing authorisation is relevant, and in line with provisions of Article 14-a of Regulation (EC) No 726/2004 it is supported.

4. Recommendations

Outcome

Based on the CHMP review of data on quality, safety and efficacy, the CHMP considers by consensus that the benefit-risk balance of Comirnaty is favourable in the following indication:

Comirnaty is indicated for active immunisation to prevent COVID-19 caused by SARS-CoV-2 virus, in individuals 16 years of age and older.

The use of this vaccine should be in accordance with official recommendations.

The CHMP therefore recommends the granting of the conditional marketing authorisation subject to the following conditions and specific obligations:

In view of the declared Public Health Emergency of International Concern and in order to ensure early supply this medicinal product is subject to a time-limited exemption allowing reliance on batch control testing conducted in the registered site(s) that are located in a third country. This exemption ceases to be valid on 31 August 2021. Implementation of EU based batch control arrangements, including the necessary variations to the terms of the marketing authorisation, has to be completed by 31 August 2021 at the latest, in line with the agreed plan for this transfer of testing. Progress reports have to be submitted on 31 March 2021 and included in the annual renewal application.

Conditions or restrictions regarding supply and use

Medicinal product subject to medical prescription.

Official batch release

In accordance with Article 114 Directive 2001/83/EC, the official batch release will be undertaken by a state laboratory or a laboratory designated for that purpose.

Other conditions and requirements of the marketing authorisation

Periodic Safety Update Reports

The requirements for submission of periodic safety update reports for this medicinal product are set out in the list of Union reference dates (EURD list) provided for under Article 107c(7) of Directive 2001/83/EC and any subsequent updates published on the European medicines web-portal.

The marketing authorisation holder shall submit the first periodic safety update report for this product within 6 months following authorisation.

Conditions or restrictions with regard to the safe and effective use of the medicinal product

Risk Management Plan (RMP)

The MAH shall perform the required pharmacovigilance activities and interventions detailed in the agreed RMP presented in Module 1.8.2 of the marketing authorisation and any agreed subsequent updates of the RMP.

An updated RMP should be submitted:

- At the request of the European Medicines Agency;
- Whenever the risk management system is modified, especially as the result of new information being received that may lead to a significant change to the benefit/risk profile or as the result of an important (pharmacovigilance or risk minimisation) milestone being reached.

Specific Obligation to complete post-authorisation measures for the conditional marketing authorisation

This being a conditional marketing authorisation and pursuant to Article 14-a of Regulation (EC) No 726/2004, the MAH shall complete, within the stated timeframe, the following measures:

Description	Due date
In order to complete the characterisation of the active substance and finished product, the MAH should provide additional data.	July 2021. Interim reports: 31 March 2021
In order to ensure consistent product quality, the MAH should provide additional information to enhance the control strategy, including the active substance and finished product specifications.	July 2021. Interim reports: March 2021
In order to confirm the consistency of the finished product manufacturing process, the MAH should provide additional validation data.	March 2021
In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the MAH should provide additional information about the synthetic process and control strategy for the excipient ALC-0315.	July 2021. Interim reports: January 2021, April 2021.
In order to confirm the purity profile and ensure comprehensive quality control and batch-to-batch consistency throughout the lifecycle of the finished product, the MAH should provide additional information about the synthetic process and control strategy for the excipient ALC-0159.	July 2021. Interim reports: January 2021, April 2021.
In order to confirm the efficacy and safety of Comirnaty, the MAH should submit the final Clinical Study Report for the randomized, placebo-controlled, observer-blind study C4591001.	December 2023

New Active Substance Status

Based on the CHMP review of the available data, the CHMP considers that single-stranded, 5'-capped messenger RNA (mRNA) produced using a cell-free in vitro transcription from the corresponding DNA templates, encoding the viral spike (S) protein of SARS-CoV-2 is a new active substance as it is not a constituent of a medicinal product previously authorised within the European Union.

1. Executive Summary

On November 20, 2020, Pfizer and BioNTech (the Sponsor) submitted an Emergency Use Authorization (EUA) request to FDA for an investigational COVID-19 vaccine (BNT162b2) intended to prevent COVID-19 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The vaccine is based on the SARS-CoV-2 spike glycoprotein (S) antigen encoded by RNA and formulated in lipid nanoparticles (LNPs). The proposed use under an EUA is "for active immunization for the prevention of COVID-19 caused by SARS-CoV-2 in individuals 16 years of age and older." The proposed dosing regimen is 2 doses, 30 µg each, administered 21 days apart.

The EUA request includes safety and efficacy data from an ongoing phase 3 randomized, double-blinded and placebo-controlled trial of BNT162b2 in approximately 44,000 participants. The primary efficacy endpoint is incidence of COVID-19 among participants without evidence of SARS-CoV-2 infection before or during the 2-dose vaccination regimen. In a mid-November analysis of 36,621 participants randomized 1:1 to vaccine or placebo who were included in the per-protocol efficacy analysis population of participants without evidence of SARS-CoV-2 infection prior to 7 days after completion of the vaccination regimen, efficacy in preventing confirmed COVID-19 occurring at least 7 days after the second dose of vaccine was 95.0%, with 8 COVID-19 cases in the vaccine group and 162 COVID-19 cases in the placebo group. Subgroup analyses of the primary efficacy endpoint showed similar efficacy point estimates across age groups, genders, racial and ethnic groups, and participants with medical comorbidities associated with high risk of severe COVID-19. Secondary efficacy analyses suggested benefit of the vaccine in preventing severe COVID-19, in preventing COVID-19 following the first dose, and in preventing COVID-19 in individuals with prior SARS-CoV-2 infection, although available data for these outcomes did not allow for firm conclusions.

Safety data from approximately 38,000 participants ≥16 years of age randomized 1:1 to vaccine or placebo with a median of 2 months of follow up after the second dose suggest a favorable safety profile, with no specific safety concerns identified that would preclude issuance of an EUA. Available safety data from all participants enrolled through the November 14, 2020 data cut-off (N=43,252, which includes late enrollment of additional adolescent and adult participants), was consistent with the safety profile for the approximately 38,000 participants with median follow-up of 2 months and also did not raise specific safety concerns. The most common solicited adverse reactions were injection site reactions (84.1%), fatigue (62.9%), headache (55.1%), muscle pain (38.3%), chills (31.9%), joint pain (23.6%), fever (14.2%); severe adverse reactions occurred in 0.0% to 4.6% of participants, were more frequent after Dose 2 than after Dose 1, and were generally less frequent in participants ≥55 years of age (≤ 2.8%) as compared to younger participants (≤4.6%). The frequency of serious adverse events was low (<0.5%), without meaningful imbalances between study arms. Among non-serious unsolicited adverse events, there was a numerical imbalance of four cases of Bell's palsy in the vaccine group compared with no cases in the placebo group, though the four cases in the vaccine group do not represent a frequency above that expected in the general population. Otherwise, there were no notable patterns or numerical imbalances between treatment groups for specific categories of non-serious adverse events (including other neurologic, neuro-inflammatory, and thrombotic events) that would suggest a causal relationship to BNT162b2 vaccine. With the exception of more frequent, generally mild to moderate reactogenicity in participants <55 years of age, the safety profile of BNT162b2 was generally similar across age groups, genders, ethnic and racial groups, participants with or without medical comorbidities, and participants with or without evidence of prior SARS-CoV-2 infection at enrollment.

This meeting of the Vaccines and Related Biological Products Advisory Committee (VRBPAC) is being convened to discuss and provide recommendations on whether:

- based on the totality of scientific evidence available, it is reasonable to believe that the Pfizer-BioNTech COVID-19 Vaccine may be effective in preventing COVID-19 in individuals 16 years of age and older, and
- the known and potential benefits of the Pfizer-BioNTech COVID-19 Vaccine outweigh its known and potential risks for use in individuals 16 years of age and older.

The committee will also discuss what additional studies should be conducted by the vaccine manufacturer following issuance of the EUA to gather further data on the safety and effectiveness of this vaccine.

2. Background

2.1. SARS-CoV-2 Pandemic

The SARS-CoV-2 pandemic presents an extraordinary challenge to global health and, as of November 30, 2020, has caused more than 60 million cases of COVID-19 and claimed the lives of 1.5 million people worldwide. In the United States, over 13 million cases have been reported to the Centers for Disease Control and Prevention (CDC), with over 260,000 deaths. Confirmed cases and mortality continue to rise globally. On January 31, 2020, the U.S. Secretary of Health and Human Services (HHS) declared a public health emergency related to COVID-19 and mobilized the Operating Divisions of HHS. Following the World Health Organization's declaration of the novel coronavirus pandemic on March 11, 2020, the U.S. President declared a national emergency in response to COVID-19 on March 13, 2020. Vaccines to protect against COVID-19 are critical to mitigate the current SARS-CoV-2 pandemic and to prevent future disease outbreaks.

SARS-CoV-2 is a novel, zoonotic coronavirus that emerged in late 2019 in patients with pneumonia of unknown cause.[1] The virus was named SARS-CoV-2 because of its similarity to the coronavirus responsible for severe acute respiratory syndrome (SARS-CoV, a lineage B betacoronavirus).[2] SARS-CoV-2 is an enveloped, positive sense, single stranded RNA virus sharing more than 70% of its sequence with SARS-CoV, and ~50% with the coronavirus responsible for Middle Eastern respiratory syndrome (MERS-CoV).[3] The SARS-CoV-2 spike glycoprotein (S), which is a main target for neutralizing antibody, binds to its receptor human angiotensin converting enzyme 2 (hACE2) to initiate infection.[4] SARS-CoV-2 is the cause of COVID-19, an infectious disease with respiratory and systemic manifestations. Disease symptoms vary, with many persons presenting with asymptomatic or mild disease and some progressing to severe respiratory tract disease including pneumonia and acute respiratory distress syndrome (ARDS), leading to multiorgan failure and death.

In an attempt to prevent the spread of disease and to control the pandemic, numerous COVID-19 vaccine candidates are in development. These vaccines are based on different platforms including mRNA and DNA technologies and include viral vectored, subunit, inactivated, and live attenuated vaccines. Most COVID-19 candidate vaccines express the spike protein or parts of the spike protein, i.e., the receptor binding domain (RBD), as the immunogenic determinant.

2.2. EUA Request for the Pfizer and BioNTech COVID-19 Vaccine BNT162b2

Pfizer, in partnership with BioNTech Manufacturing GmbH, is developing a vaccine to prevent COVID-19 which is based on the SARS-CoV-2 spike glycoprotein (S) antigen encoded by RNA and formulated in lipid nanoparticles (LNP). The Pfizer-BioNTech COVID-19 Vaccine (also referred to as BNT162b2) is administered intramuscularly as a 2-dose series spaced 21 days apart at a dose of 30 µg each. The vaccine is supplied as a multi-dose vial (5 doses) containing a frozen suspension (-80°C to -60°C) of BNT162b2 that must be thawed and diluted with 1.8 mL of sterile 0.9% sodium chloride, allowing for five 0.3 mL doses. The vaccine is preservative free.

A phase 3 randomized and placebo-controlled trial using BNT162b2 in approximately 44,000 participants is currently ongoing to evaluate the vaccine's safety and efficacy. Vaccine efficacy for the primary endpoint against confirmed COVID-19 occurring at least 7 days after the second dose was 95.0% with 8 COVID-19 cases in the vaccine group compared to 162 COVID-19 cases in the placebo group. Data from about 38,000 participants randomized 1:1 with a median of 2 months of follow-up after the second dose of vaccine showed a favorable safety profile at a dose of 30 µg in participants 16 years of age and older. On November 20, 2020, Pfizer and BioNTech submitted an EUA request to FDA for its investigational COVID-19 vaccine (BNT162b2) intended to prevent COVID-19 caused by SARS-CoV-2.

2.3. U.S. Requirements to Support Issuance of an EUA for a Biological Product

Based on the declaration by the Secretary of HHS that the COVID-19 pandemic constitutes a public health emergency with a significant potential to affect national security or the health and security of United States citizens living abroad, FDA may issue an EUA after determining that certain statutory requirements are met (section 564 of the FD&C Act (21 U.S.C. 360bbb-3)).[5]

- The chemical, biological, radiological, or nuclear (CBRN) agent referred to in the March 27, 2020 EUA declaration by the Secretary of HHS (SARS-CoV-2) can cause a serious or life-threatening disease or condition.
- Based on the totality of scientific evidence available, including data from adequate and well-controlled trials, if available, it is reasonable to believe that the product may be effective to prevent, diagnose, or treat such serious or life-threatening disease or condition that can be caused by SARS-CoV-2, or to mitigate a serious or life-threatening disease or condition caused by an FDA-regulated product used to diagnose, treat, or prevent a disease or condition caused by SARS-CoV-2.
- The known and potential benefits of the product, when used to diagnose, prevent, or treat the identified serious or life-threatening disease or condition, outweigh the known and potential risks of the product.
- There is no adequate, approved, and available alternative to the product for diagnosing, preventing, or treating the disease or condition.

If these criteria are met, under an EUA, FDA can allow unapproved medical products (or unapproved uses of approved medical products) to be used in an emergency to diagnose, treat, or prevent serious or life-threatening diseases or conditions caused by threat agents. FDA has been providing regulatory advice to COVID-19 vaccine manufacturers regarding the data needed to determine that a vaccine's benefit outweigh its risks. This includes demonstrating that manufacturing information ensures product quality and consistency along with data from at least one phase 3 clinical trial demonstrating a vaccine's safety and efficacy in a clear and compelling manner.

In the event an EUA is issued for this product, it would still be considered unapproved and it would be under further investigation (under an Investigational New Drug Application) until it is licensed under a Biologics License Application (BLA). Licensure of a COVID-19 vaccine will be based on review of additional manufacturing, efficacy, and safety data, providing greater assurance of the comparability of licensed product to product tested in the clinical trials, greater assurance of safety based on larger numbers of vaccine recipients who have been followed for a longer period of time, and additional information about efficacy that addresses, among other questions, the potential for waning of protection over time.

2.4. Applicable Guidance for Industry

Risk and benefit considerations are unique for COVID-19 vaccines, given that an EUA may be requested to allow for a vaccine's rapid and widespread deployment for administration to millions of individuals, including healthy people. FDA published in October 2020 guidance for industry entitled "Emergency Use Authorization for Vaccines to Prevent COVID-19" (Appendix C, page 53) describing FDA's current recommendations regarding the manufacturing, nonclinical, and clinical data and information needed under section 564 of the FD&C Act to support the issuance of an EUA for an investigational vaccine to prevent COVID-19, including a discussion of FDA's current thinking regarding the circumstances under which an EUA for a COVID-19 vaccine would be appropriate.

2.5. Safety and Effectiveness Information Needed to Support an EUA

Effectiveness data

Issuance of an EUA requires a determination that the known and potential benefits of the vaccine outweigh the known and potential risks. For a preventive COVID-19 vaccine to be potentially administered to millions of individuals, including healthy individuals, data adequate to inform an assessment of the vaccine's benefits and risks and support issuance of an EUA would include meeting the prespecified success criteria for the study's primary efficacy endpoint, as described in the guidance for industry entitled "Development and Licensure of Vaccines to Prevent COVID-19" (i.e., a point estimate for a placebo-controlled efficacy trial of at least 50%, with a lower bound of the appropriately alpha-adjusted confidence interval around the primary efficacy endpoint point estimate of >30%).[6]

Safety data

An EUA request for a COVID-19 vaccine should include all safety data accumulated from studies conducted with the vaccine, with data from phase 1 and 2 focused on serious adverse events, adverse events of special interest, and cases of severe COVID-19 among study participants. Phase 3 safety data should include characterization of reactogenicity (common and expected adverse reactions shortly following vaccination) in a sufficient number of participants from relevant age groups and should include a high proportion of enrolled participants (numbering well over 3,000) followed for serious adverse events and adverse events of special interest for at least one month after completion of the full vaccination regimen. The phase 1 and 2 safety data likely will be of a longer duration than the available safety data from the phase 3 trial at the time of submission of an EUA request and thus, are intended to complement the available data from safety follow-up from ongoing phase 3 studies.

Phase 3 Follow-up

Data from phase 3 studies should include a median follow-up duration of at least 2 months after completion of the full vaccination regimen to help provide adequate information to assess a vaccine's benefit-risk profile. From a safety perspective, a 2-month median follow-up following completion of the full vaccination regimen will allow identification of potential adverse events that were not apparent in the immediate postvaccination period. Adverse events considered plausibly linked to vaccination generally start within 6 weeks of vaccine receipt.[7] Therefore, a 2-month follow-up period may allow for identification of potential immune-mediated adverse events that began within 6 weeks of vaccination. From the perspective of vaccine efficacy, it is important to assess whether protection mediated by early responses has not started to wane. A 2-month median follow-up is the shortest follow-up period to achieve some confidence that any protection against COVID-19 is likely to be more than short-lived. The EUA request should include a plan for active follow-up for safety (including deaths, hospitalizations, and other serious or clinically significant adverse events) among individuals administered the vaccine under an EUA in order to inform ongoing benefit-risk determinations to support continuation of the EUA.

2.6. Continuation of clinical trials following issuance of an EUA for a COVID-19 vaccine

FDA does not consider availability of a COVID-19 vaccine under EUA, in and of itself, as grounds for immediately stopping blinded follow-up in an ongoing clinical trial or grounds for offering vaccine to all placebo recipients. To minimize the risk that use of an unapproved vaccine under EUA will interfere with long-term assessment of safety and efficacy in ongoing trials, it is critical to continue to gather data about the vaccine even after it is made available under EUA. An EUA request should therefore include strategies that will be implemented to ensure that ongoing clinical trials of the vaccine are able to assess long-term safety and efficacy (including evaluating for vaccine-associated enhanced respiratory disease and decreased effectiveness as immunity wanes over time) in sufficient numbers of participants to support vaccine licensure. These strategies should address how ongoing trial(s) will handle loss of follow-up information for study participants who choose to withdraw from the study in order to receive the vaccine under an EUA.

FDA is aware that some COVID-19 vaccine developers may wish to immediately unblind their trials upon issuance of an EUA in order to rapidly provide vaccine to trial participants who received placebo. Some developers have proposed maintaining blinding in a crossover design that provides vaccine to previous placebo recipients and placebo to previous vaccine recipients. Such strategies would impact collection of longer-term placebo-controlled safety data and evaluation of the duration of vaccine efficacy. Ethical and scientific issues associated with offering vaccination to placebo recipients have been discussed in recent statements and articles.[8-10]

2.7. Previous Meetings of the VRBPAC to Discuss Vaccines to Prevent COVID-19

On October 22, 2020, the VRBPAC met in open session, to discuss, in general, the development, authorization and/or licensure of vaccines to prevent COVID-19. No specific application was discussed at this meeting. Topics discussed at the meeting included:

- FDA's approach to safety and effectiveness, and chemistry, manufacturing and control (CMC) data as outlined in the respective guidance documents

- Considerations for continuation of blinded Phase 3 clinical trials if an EUA has been issued for an investigational COVID-19 vaccine
- Studies following licensure and/or issuance of an EUA for COVID-19 vaccines to:
  - Further evaluate safety, effectiveness and immune markers of protection
  - Evaluate the safety and effectiveness in specific populations.

3. Topics for VRBPAC Discussion

The Vaccines and Related Biological Products Advisory Committee will convene on December 10, 2020, to discuss and provide recommendations on whether:

- based on the totality of scientific evidence available, it is reasonable to believe that the Pfizer-BioNTech COVID-19 Vaccine may be effective in preventing COVID-19 in individuals 16 years of age and older, and
- the known and potential benefits of the Pfizer-BioNTech COVID-19 Vaccine outweigh its known and potential risks for use in individuals 16 years of age and older.

The committee will also discuss what additional studies should be conducted by the vaccine manufacturer following issuance of the EUA to gather further data on the safety and effectiveness of this vaccine.

4. Pfizer-BioNTech COVID-19 Vaccine (BNT162b2)

4.1. Vaccine Composition, Dosing Regimen

The Pfizer-BioNTech COVID-19 Vaccine is a white to off-white, sterile, preservative-free, frozen suspension for intramuscular injection. The vaccine contains a nucleoside-modified messenger RNA (modRNA) encoding the viral spike glycoprotein (S) of SARS-CoV-2. The vaccine also includes the following ingredients: lipids ((4-hydroxybutyl)azanediyl)bis(hexane-6,1-diyl)bis(2-hexyldecanoate), 2-[(polyethylene glycol)-2000]-N,N-ditetradecylacetamide, 1,2-distearoyl-sn-glycero-3-phosphocholine, and cholesterol), potassium chloride, monobasic potassium phosphate, sodium chloride, dibasic sodium phosphate dihydrate, and sucrose.

The Pfizer-BioNTech COVID-19 Vaccine is supplied as a frozen [between -80°C to -60°C (-112°F to -76°F)] multi-dose (5-dose) vial. The vaccine must be thawed and diluted in its original vial with 1.8 mL of sterile 0.9% Sodium Chloride Injection, USP prior to administration. After dilution, the vial contains 5 doses of 0.3 mL per dose. After dilution, the multiple-dose vials must be stored between 2°C to 25°C (35°F to 77°F) and used within 6 hours from the time of dilution.

The Pfizer-BioNTech COVID-19 Vaccine, BNT162b2 (30 µg), is administered intramuscularly (IM) as a series of two 30 µg doses (0.3 mL each) 21 days apart.

FDA has reviewed the CMC data submitted to date for this vaccine and has determined that the CMC information is consistent with the recommendations set forth in FDA's Guidance on Emergency Use Authorization for Vaccines to Prevent COVID-19. As such, FDA has determined that the Sponsor has provided adequate information to ensure the vaccine's quality and consistency for authorization of the product under an EUA.

4.2. Proposed Use Under EUA

The proposed indication and use of the vaccine under an EUA is "for active immunization for the prevention of COVID-19 caused by SARS-CoV-2 in individuals 16 years of age and older."

5. FDA Review of Clinical Safety and Effectiveness Data

5.1. Overview of Clinical Studies

Data from two ongoing clinical studies were included in the EUA request, which are summarized in Table 1 below. Study C4591001 is a multi-center, multi-national Phase 1,2,3 randomized, blinded, placebo-controlled safety, immunogenicity, and efficacy study that is the focus of the EUA review. Study BNT162-01 is a Phase 1 study that explored various vaccine candidates and dose levels and will not be discussed in detail. A brief summary of the BNT162-01 study design and results to date is found in Appendix A, page 51.

Table 1: Clinical Trials Submitted in Support of Efficacy and Safety Determinations of the Pfizer-BioNTech COVID-19 Vaccine

Study Number/ Country	Description	BNT162b2 (30 µg)* participants (N)	Placebo participants (N)	Study Status
C4591001 USA, Argentina, Brazil, Germany, S. Africa, Turkey	Phase 1,2,3 randomized, placebo-controlled, observer-blind; to evaluate safety, immunogenicity and efficacy of COVID-19 vaccine	Phase 1: 24 Phase 2/3: 21823	Phase 1: 6 Phase 2/3: 21828	Ongoing
BNT162-01 Germany	Phase 1/2 randomized, open-label; to evaluate safety and immunogenicity, dose escalation	12	0	Ongoing

N= total number of randomized participants as of November 14, 2020. Placebo: saline.
*Phase 1 studies included additional participants vaccinated with other dose levels and other mRNA vaccine candidates.
Studies C4591001 and BNT162-01 started in April 2020 (first participant, first visit).

5.2. Study C4591001

5.2.1. Design

Study C4591001 is an ongoing, randomized, placebo-controlled, phase 1/2/3 study being conducted in the US, Argentina, Brazil, Germany, South Africa and Turkey. Initially the study was designed as a phase 1/2 study in healthy adults in the US for vaccine candidate and dosage selection, immunogenicity and preliminary efficacy, but the protocol was revised to expand the study design for inclusion of a phase 2/3 portion to evaluate clinical disease endpoint efficacy in individuals 12 years of age and older in the US and additional sites outside of the US.

In phase 1, two age groups were evaluated in separate cohorts, younger participants 18 through 55 years of age (N=45) and older participants 65 through 85 years of age (N=45). The study population included healthy men and women and excluded participants at high risk of SARS-CoV-2 infection or with serological evidence of prior or current SARS-CoV-2 infection. Two different vaccine candidates were evaluated, and younger participants received escalating dose levels with progression to subsequent dose levels and evaluation of escalating dose levels in the older age group (65 through 85 years), based on recommendations from an internal review committee that reviewed safety and immunogenicity data. For each vaccine candidate and dose

level, participants were randomized 4:1, such that 12 participants received the vaccine candidate and 3 participants received placebo. Review of the safety and immunogenicity from phase 1, in combination with data from Study BNT162-01 (See Section 10), supported the final vaccine candidate and dose level (BNT162b2 at 30 µg, given 21 days apart) to proceed into phase 2/3.

In phase 2/3, participants were enrolled with stratification by age (younger adults: 18 through 55 years of age; older adults: over 55 years of age) and a goal of 40% enrollment in the older adult age group. Adolescents were added to the protocol, based on review of safety data in younger adults enrolled in the ongoing study, so the age strata were revised as follows: 12 through 15 years of age, 16 through 54 years of age, and 55 years of age and older. The study population for phase 2/3 includes participants at higher risk for acquiring COVID-19 and at higher risk of severe COVID-19 disease, such as participants working in the healthcare field, participants with autoimmune disease, and participants with chronic but stable medical conditions such as hypertension, asthma, diabetes, and infection with HIV, hepatitis B or hepatitis C. Participants were randomized 1:1 to receive 2 doses of either BNT162b2 or placebo, 21 days apart. The phase 2 portion of the study evaluated reactogenicity and immunogenicity for 360 participants enrolled early-on, and these participants also contribute to the overall efficacy and safety data in the phase 3 portion. The ongoing phase 3 portion of the study is evaluating the safety and efficacy of BNT162b2 for the prevention of COVID-19 disease occurring at least 7 days after the second dose of vaccine. Efficacy is being assessed throughout a participant's follow-up in the study through surveillance for potential cases of COVID-19. If, at any time, a participant develops acute respiratory illness, an illness visit occurs. Assessments for illness visits include a nasal (midturbinate) swab, which is tested at a central laboratory using a reverse transcription-polymerase chain reaction (RT-PCR) test (e.g., Cepheid; FDA authorized under EUA), or other sufficiently validated nucleic acid amplification-based test (NAAT), to detect SARS-CoV-2. The central laboratory NAAT result is used for the case definition, unless it is not possible to test the sample at the central laboratory. In that case, the following NAAT results are acceptable: Cepheid Xpert Xpress SARS-CoV-2Roche cobas SARS-CoV-2 real-time RT-PCR test (EUA200009/A001) Abbott Molecular/RealTime SARS-CoV-2 assay (EUA200023/A001).

The study design includes planned interim analyses of the first primary efficacy endpoint at pre-specified numbers of COVID-19 cases (at least 62, 92, and 120 cases), and all primary and secondary efficacy endpoints were analyzed in the final efficacy analysis after at least 164 COVID-19 cases were accrued (see Statistical Analysis section, below). Participants are expected to participate for a maximum of approximately 26 months.

Primary Efficacy Endpoints

Study C4591001 has two primary endpoints

First primary endpoint: COVID-19 incidence per 1000 person-years of follow-up in participants without serological or virological evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2

Second primary endpoint: COVID-19 incidence per 1000 person-years of follow-up in participants with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥7 days after Dose 2

Secondary Efficacy Endpoints

Study C4591001 has secondary endpoints based on different approaches to COVID-19 case evaluation criteria as follows:

COVID-19 confirmed at least 14 days after Dose 2: COVID-19 incidence per 1000 person-years of follow up in participants either (1) without or (2) with and without serological or virological evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed ≥14 days after Dose 2

Severe COVID-19: incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed either (1) ≥7 days after Dose 2 or (2) ≥14 days after Dose 2

CDC-defined COVID-19: incidence per 1000 person-years of follow-up in participants either (1) without or (2) with and without evidence of past SARS-CoV-2 infection before and during vaccination regimen – cases confirmed either (1) ≥7 days after Dose 2 or (2) ≥14 days after Dose 2.

For the primary efficacy endpoint, the case definition for a confirmed COVID-19 case was the presence of at least one of the following symptoms and a positive SARS-CoV-2 NAAT within 4 days of the symptomatic period:

- Fever;
- New or increased cough;
- New or increased shortness of breath;
- Chills;
- New or increased muscle pain;
- New loss of taste or smell;
- Sore throat;
- Diarrhea;
- Vomiting.

For a secondary efficacy endpoint, a second definition, which may be updated as more is learned about COVID-19, included the following additional symptoms defined by CDC (listed at https://www.cdc.gov/coronavirus/2019-ncov/symptoms-testing/symptoms.html):

- Fatigue;
- Headache;
- Nasal congestion or runny nose;
- Nausea.

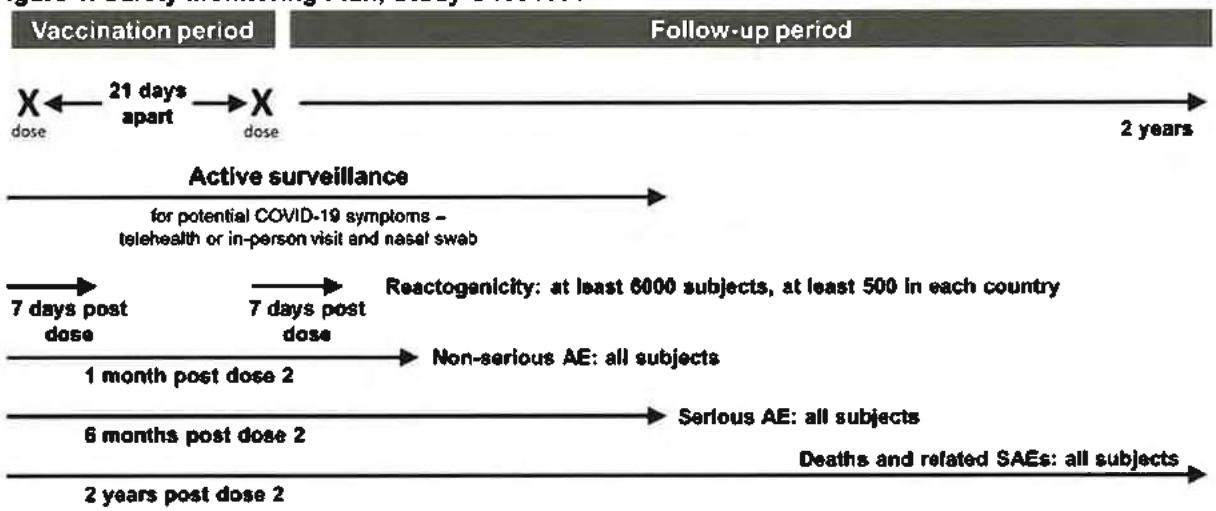
For another secondary endpoint, the case definition for a severe COVID-19 case was a confirmed COVID-19 case with at least one of the following:

- Clinical signs at rest indicative of severe systemic illness (RR ≥30 breaths per minute, HR ≥125 beats per minute, SpO2 ≤93% on room air at sea level, or PaO2/FiO2 <300 mm Hg);
- Respiratory failure (defined as needing high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO);
- Evidence of shock (SBP <90 mm Hg, DBP <60 mm Hg, or requiring vasopressors)
- Significant acute renal, hepatic, or neurologic dysfunction;
- Admission to an ICU;
- Death.

Evaluation of Safety

The primary safety objective for all phases was to describe the safety of BNT162 vaccine(s) in healthy adults after 1 or 2 doses. All phase 1 participants (n=30), and then 6653 U.S. participants (360 phase 2, 6293 phase 3) and the first ~500 phase 3 participants/per country with enrollment through October 9, 2020 (Argentina, Brazil and South Africa) recorded local reactions, systemic events, and antipyretic/pain medication usage from Day 1 through Day 7 after each dose. Unsolicited adverse events (AEs) are collected from Dose 1 to 1 month after the last dose and serious AEs (SAEs) from Dose 1 to 6 months after the last dose. Figure 1 below shows the study safety monitoring plan.

Figure 1. Safety Monitoring Plan, Study C4591001



Reactogenicity assessments included solicited injection site reactions (pain, redness, swelling) and systemic AEs (fever, fatigue, headache, chills, vomiting, diarrhea, new or worsened muscle pain, and new or worsened joint pain), and antipyretic/pain medication use were recorded in an e-diary. At the data cutoff date for the EUA, reactogenicity events were not collected from adolescents 16 to 17 years of age (enrolled prior to the implementation of Protocol Amendment 9, finalized on 29 October 2020) using an e-diary but were detected and reported as unsolicited AEs. For any phase 3 participants who were not in the reactogenicity subset, local reactions and systemic events consistent with reactogenicity were detected and reported as unsolicited AEs. HIV-positive participants and adolescents 12 through 15 years of age were included in the reactogenicity subset with implementation of protocol amendment 6 (finalized on September 8, 2020) and amendment 7 (finalized on October 6, 2020), respectively. Solicited reactogenicity data in adolescents 16-17 years of age are not available for the reporting period. Reactogenicity data from a total of 100 adolescents 12 through 15 years of age enrolled in C4591001 phase 2/3 were provided in the EUA submission. However, the Sponsor did not request inclusion of this age group in the EUA because the available data, including number of participants and follow-up duration, were insufficient to support favorable a benefit-risk determination at this time. Therefore, the reactogenicity data for participants 12 through 15 years of age are not presented in this document.

Clinical laboratory tests were assessed in phase 1 at 1-week postvaccination. The planned safety follow-up for currently enrolled adolescents and adults is through 24 months after vaccination #2.

Potential COVID-19 illnesses and their sequelae were not to be reported as AEs, with the exception of illnesses that met regulatory criteria for seriousness and were not confirmed to be COVID-19. These illnesses were evaluated and reported as SAEs.

In phase 2/3, monitoring for risk of vaccine-enhanced disease was performed by an unblinded team supporting the Data Monitoring Committee that reviewed cases of severe COVID-19 as they were received and reviewed AEs at least weekly for additional potential cases of severe COVID-19. The stopping rule was triggered when the 1-sided probability of observing the same or a more extreme case split was 5% or less when the true incidence of severe disease was the same for vaccine and placebo participants, and alert criteria were triggered when this probability was less than 11%.

Analysis Populations

For the purposes of analysis, the following populations are defined:

Population	Description
Enrolled	All participants who have a signed informed consent document.
Randomized	All participants who are assigned a randomization number.
Evaluable efficacy	All eligible randomized participants who receive all vaccination(s) as randomized within the predefined window and have no other important protocol deviations as determined by the clinician.
All-available efficacy	1. All randomized participants who receive at least 1 vaccination. 2. All randomized participants who complete 2 vaccination doses.

Phase 2/3 safety analysis populations were as follows:

- Phase 2/3 all-enrolled population: composed of a total of 43,448 (21720 vaccine, 21728 placebo) participants ≥16 years of age, regardless of duration of follow-up, for whom written informed consent was obtained. Initial enrollment included individuals 18 years and older, then included individuals as young as 16 years of age and individuals with known HIV (protocol amendment 6; finalized on September 8, 2020). As of November 14, 2020, 43.9% and 79.5% of vaccine recipients completed at least 2 months (≥8 weeks) and at least 1 month (≥4 weeks), respectively, of safety follow-up after Dose 2. The percentages of placebo recipients completing at least 2 months (≥8 weeks) and at least 1 month (≥4 weeks) were similar to the vaccine group.

- Phase 2/3 safety population (median follow-up time of 2 months after vaccination #2): comprised of a total of 37586 (18801 vaccine,18785 placebo) participants >16 years of age enrolled by October 9, 2020 and received at least 1 dose of study vaccine or placebo; overall, 98.1% of participants completed the 2-dose series. As of November 14, 2020, 50.6% and 91.6% of vaccine recipients completed at least 2 months (>8 weeks) and at least 1 month (>4 weeks), respectively, of safety follow-up after Dose 2. The percentages of placebo recipients completing at least 2 months (>8 weeks) and at least 1 month (>4 weeks) were similar to the vaccine group. A total of 283 (138 vaccine,145 placebo) individuals were 16 to <18 years of age. HIV-positive individuals were included in the all-enrolled population, but not the phase 2/3 safety population because the number of participants enrolled by October 9, 2020 was small (n=120) and the median duration of safety follow-up was short.

5.2.2. FDA Assessment of Phase 2/3 Follow-Up Duration

Study C4591001 initially enrolled approximately 30,000 participants and then several months later began enrollment of approximately 14,000 additional participants, including adolescents and participants with chronic, stable HIV, hepatitis B, or hepatitis C infections. Because of the gap in enrollment, the entire enrolled study population had a median follow-up of less than 2 months as of the EUA submission data cut-off date of November 14, 2020. However, the analyses submitted to support this EUA request meet the expectation for median duration of follow-up time, as follows:

- Submitted safety analyses for participants enrolled through October 9, 2020, and followed through November 14, 2020 (referred to by Pfizer and in this document as the phase 2/3 safety population and including a total of 37,586 participants), represent a median follow-up of 2 months. Additionally, this safety database is larger than for the initial planned enrollment of approximately 30,000 participants.

- The date for data cut-off for the first interim analysis for efficacy was November 4, 2020, when a total of 94 confirmed COVID-19 cases were accrued. All of the participants included in the first interim efficacy analysis had at least 7 days of follow-up after Dose 2, and thus were enrolled no later than October 7, 2020. All participants in the first interim efficacy analysis were therefore included in the phase 2/3 safety population defined above. Although the median follow-up duration for participants included in the first interim efficacy analysis was slightly less than 2 months as of November 4, 2020, these participants were also included in the final efficacy analyses with data cut-off of November 14, 2020, which extended the median follow-up for these participants to greater than 2 months. The results of the final efficacy analysis on data to November 14, 2020, indicate that the conclusions from the first interim efficacy analysis would not change when including additional follow-up to November 14, 2020.

The date for data cut-off for the final efficacy analysis was November 14, 2020, when a total of 170 confirmed COVID-19 cases were accrued. As noted above, the median follow-up duration after completion of the full vaccination regimen for all participants enrolled at that time was less than 2 months for both safety and efficacy populations, due to a gap in enrollment. Because the data for the final efficacy analysis could be submitted in support of the EUA request and could provide data from a greater number of participants than from the interim analysis, FDA has focused its review on the efficacy data from the final efficacy analyses. Additional safety analyses from this larger database of all enrolled participants were also reviewed to evaluate for differences compared with the smaller phase 2/3 safety population.

5.2.3. Subject Disposition and Inclusion in Analysis Populations

Disposition tables are presented below in Table 2 (efficacy analysis populations) and Table 3 (phase 2/3 safety population). Overall, few participants were discontinued or lost to follow-up, and these and other analysis population exclusions were generally balanced between treatment groups. Of 43,448 participants in the phase 2/3 all-enrolled population, 94.2% of vaccine recipients and 94.1% of placebo recipients completed 2 doses (data not shown).

Pfizer-BioNTech COVID-19 Vaccine
VRBPAC Briefing Document

Table 2. Efficacy Populations, Treatment Groups as Randomized

	BNT162b2 (30 µg) n[a] (%)	Placebo n[a] (%)	Total n[a] (%)
Randomized[b]	21823 (100.0)	21828 (100.0)	43651 (100.0)
Dose 1 all-available efficacy population	21768 (99.7)	21783 (99.8)	43551 (99.8)
Participants without evidence of infection before Dose 1	20314 (93.1)	20296 (93.0)	40610 (93.0)
Participants excluded from Dose 1 all-available efficacy population	55 (0.3)	45 (0.2)	100 (0.2)
Reason for exclusion[c]			
Did not receive at least 1 vaccination	54 (0.2)	45 (0.2)	99 (0.2)
Did not provide informed consent	1 (0.0)	0	1 (0.0)
Dose 2 all-available efficacy population	20566 (94.2)	20536 (94.1)	41102 (94.2)
Participants without evidence of infection prior to 7 days after Dose 2	18701 (85.7)	18627 (85.3)	37328 (85.5)
Participants without evidence of infection prior to 14 days after Dose 2	18678 (85.6)	18563 (85.0)	37241 (85.3)
Participants excluded from Dose 2 all-available efficacy population	1257 (5.8)	1292 (5.9)	2549 (5.8)
Reason for exclusion[c]			
Did not receive 2 vaccinations	1256 (5.8)	1292 (5.9)	2548 (5.8)
Did not provide informed consent	1 (0.0)	0	1 (0.0)
Evaluable efficacy (7 days) population	20033 (91.8)	20244 (92.7)	40277 (92.3)
Evaluable efficacy (14 days) population	20033 (91.8)	20243 (92.7)	40276 (92.3)
Participants excluded from evaluable efficacy (7 days) population	1790 (8.2)	1584 (7.3)	3374 (7.7)
Participants excluded from evaluable efficacy (14 days) population	1790 (8.2)	1585 (7.3)	3375 (7.7)
Reason for exclusion[c]			
Randomized but did not meet all eligibility criteria	36 (0.2)	26 (0.1)	62 (0.1)
Did not provide informed consent	1 (0.0)	0	1 (0.0)
Did not receive all vaccinations as randomized or did not receive Dose 2 within the predefined window (19-42 days after Dose 1)	1550 (7.1)	1561 (7.2)	3111 (7.1)
Had other important protocol deviations on or prior to 7 days after Dose 2	311 (1.4)	60 (0.3)	371 (0.8)
Had other important protocol deviations on or prior to 14 days after Dose 2	311 (1.4)	61 (0.3)	372 (0.9)

[a]n = Number of participants with the specified characteristic.
[b]These values are the denominators for the percentage calculations.
[c]Participants may have been excluded for more than 1 reason.
Note: 100 participants 12 through 15 years of age with limited follow-up are included in the randomized population (49 in the vaccine group and 51 in the placebo group). Some of these subjects were included in the denominators of efficacy analyses, depending on the population analyzed, but did not contribute primary endpoint cases and do not affect efficacy conclusions for ages 16 years and above.

Table 3. Disposition of All Randomized Participants, Phase 2/3 Safety Population

Treatment Group	BNT162b2 N=18904 n (%)	Placebo N=18892) n (%)	Total N=37796 n (%)
Randomized	18904 (100.0)	18892 (100.0)	37796 (100.0)

Refused further study procedures	0	1 (0.0)	1 (0.0)

Source: EUA 27036, amendment 3, Table 2; c4591001-safety-tables-cos-reacto.pdf, page 43.
Note: One participant was randomized but did not sign informed consent and therefore not included in any analysis population.
Note: 120 HIV-positive participants included in this table. HIV population analyses were summarized separately from analyses based on the phase 2/3 safety population, but included in the all-enrolled poplation analyses presented in this briefing document.
%:n/N. n = number of subjects with the specified characteristic. N = number of participants ≥16 years of age enrolled by October 9, 2020, including 120 HIV-positive participants, and received at least 1 dose of study vaccine or placebo. N is the denominator used for the percentage calculations.
Data analysis cutoff date: November 14, 2020

The numbers of randomized participants contributing to efficacy analyses presented in this document include 100 participants 12 through 15 years of age (49 in the vaccine group and 51 in the placebo group) who had limited follow-up at the time of the November 14, 2020 data cut-off. However, the sponsor did not include this age group in the EUA request. The numbers of participants presented and used as denominators for efficacy calculations were not adjusted to remove participants 12 through 15 years of age. Because the number of participants 12 through 15 years of age is very small relative to the overall efficacy analysis populations, and no primary endpoint COVID-19 cases occurred in this age group, the vaccine efficacy conclusions are not impacted. No participants 12 through 15 years of age are included in the safety analyses. However, the safety disposition table includes 120 HIV-positive participants who were not included in the phase 2/3 safety population analyses.

5.2.4. Demographics and Other Baseline Characteristics

Overall, the phase 2/3 evaluable efficacy population included 49.4% females, 81.9% White, 9.8% African American, 4.4% Asian participants, and <3% from other racial groups; 26.2% of participants were Hispanic/Latino; 21.4% of participants were ≥65 years of age. The median age was 51 years. The most frequently reported comorbidities were obesity (35.1%), diabetes (with and without chronic complications, 8.4%) and pulmonary disease (7.8%). Geographically, 76.7% of participants were from the US, 15.3% from Argentina, 6.1% from Brazil, and 2% from South Africa.

The demographic characteristics among vaccine and placebo participants in the all-available efficacy population were similar to the evaluable efficacy population. Please refer to the table below.

Table 4. Demographic Characteristics, Participants With or Without Evidence of Infection Prior to 7 Days After Dose 2, Evaluable Efficacy (7 Days) Population

Characteristic	BNT162b2 (N[a]=20033) N[b] (%)	Placebo (N[a]=20244) N[b] (%)	Total (N[a]=40277) N[b] (%)
Sex: Female	9794 (48.9)	10107 (49.9)	19901 (49.4)

Comorbidities[c]: Yes	9278 (46.3)	9314 (46.0)	18592 (46.2)
Comorbidities: No	10755 (53.7)	10930 (54.0)	21685 (53.8)
Comorbidity: Obesity	6934 (34.6)	7093 (35.0)	14027 (34.8)

[a].N = number of participants in the specified group, or the total sample. This value is the denominator for the percentage calculations.
[b].n = number of participants with the specified characteristic.
[c]. Number of participants who have 1 or more comorbidities that increase the risk of severe COVID-19 disease: defined as patients who had at least one of the Charlson comorbidity index (Appendix B, page 52) category or obesity only (BMI ≥30 kg/m^2).

Overall, the phase 2/3 safety population included 83.1% White, 9.1% African American, 4.3% Asian participants, and <3% from other racial groups; 28.0% of participants were Hispanic/Latino; 21.6% of participants were >65 years of age. The median age was 52 years, and safety data from a total of 103 participants 16 and 17 years of age were included in this submission. The most frequently reported comorbidities were obesity (35.1%), diabetes (without chronic complications, 7.8%) and chronic pulmonary disease (7.8%). Geographically, 76.7% of participants were from the US, 15.3% from Argentina, 6.1% from Brazil, and 2.0% from South Africa.

The demographic characteristics among vaccine and placebo participants in the all-enrolled population were similar and were also enrolled from sites in Germany (1%) and Turkey (1%). There were no significant imbalances in demographic and other baseline characteristics between the all-enrolled population and phase 2/3 safety population with median 2-month follow-up.

5.2.5. Vaccine Efficacy

Primary Efficacy Analyses

Efficacy Results – Primary Endpoint (Evaluable Efficacy Population)

For the first primary efficacy endpoint, vaccine efficacy (VE) for BNT162b2 against confirmed COVID-19 was evaluated in participants without evidence of prior SARS-CoV-2 infection prior to 7 days after Dose 2. For the second primary efficacy endpoint, VE for BNT162b2 against confirmed COVID-19 was evaluated in participants with and without evidence of prior SARS-CoV-2 infection prior to 7 days after Dose 2. Cases were counted from 7 days after Dose 2 for both endpoints. The criterion for success was met if the posterior probability that true vaccine efficacy >30% conditioning on the available data was >99.5% at the final analysis.

For participants without evidence of SARS-CoV-2 infection prior to 7 days after Dose 2, VE against confirmed COVID-19 occurring at least 7 days after Dose 2 was 95.0%. The case split was 8 COVID-19 cases in the BNT162b2 group compared to 162 COVID-19 cases in the placebo group (Table 6). The 95% credible interval for the vaccine efficacy was 90.3% to 97.6%, indicating that the true VE is at least 90.3% with a 97.5% probability, which met the pre-specified success criterion.

Table 6. Final Analysis of Efficacy of BNT162b2 Against Confirmed COVID-19 From 7 Days After Dose 2 in Participants Without Evidence of Prior SARS-CoV-2 Infection - Evaluable Efficacy Population

Pre-specified Age Group	BNT162b2 N[a] = 18198 Cases n1[b] Surveillance Time[c] (n2[d])	Placebo N[a] =18325 Cases n1[b] Surveillance Time[c] (n2[d])	Vaccine Efficacy % (95% CI)	Met Predefined Success Criterion*
All participants	8 2.214 (17411)	162 2.222 (17511)	95.0 (90.3, 97.6)[e]	Yes
16 to 55 years	5 1.234 (9897)	114 1.239 (9955)	95.6 (89.4, 98.6)[f]	NA
> 55 years and older	3 0.980 (7500)	48 0.983 (7543)	93.7 (80.6, 98.8)[f]	NA

*Success criterion: the posterior probability that true vaccine efficacy > 30% conditioning on the available data is >99.5% at the final analysis

[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
[d] n2 = Number of participants at risk for the endpoint.
[e] Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time.
[f] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.

For participants with and without evidence of SARS-CoV-2 infection before and during vaccination regimen, VE against confirmed COVID-19 occurring at least 7 days after Dose 2 was 94.6%, with 9 and 169 cases in the BNT162b2 and placebo groups respectively (Table 7). The posterior probability was >99.99% for the true VE being greater than 30%. The 95% credible interval for the vaccine efficacy was 89.9% to 97.3%, indicating that the true VE is at least 89.9% with a 97.5% probability given the available data.

Table 7. Efficacy of BNT162b2 Against Confirmed COVID-19 From 7 Days After Dose 2 in Participants With And Without Evidence of Prior SARS-CoV-2 Infection, Evaluable Efficacy Population

Pre-specified Age Group	BNT162b2 N[a] = 19965 Cases n1[b] Surveillance Time[c] (n2[d])	Placebo N[a] =20172 Cases n1[b] Surveillance Time[c] (n2[d])	Vaccine Efficacy % (95% CI)	Met Predefined Success Criterion*
All participants	9 2.332 (18559)	169 2.345 (18708)	94.6 (89.9, 97.3)[e]	Yes
16 to 55 years	6 1.309 (10653)	120 1.317 (10738)	95.0 (88.7, 98.2)[f]	NA
>55 years and older	3 1.022 (7892)	49 1.028 (7956)	93.8 (80.9, 98.8)[f]	NA

*Success criterion: the posterior probability that true vaccine efficacy >30% conditioning on the available data is >99.5% at the final analysis
[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
[d] n2 = Number of participants at risk for the endpoint.
[e] Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time.
[f] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.

Subgroup Analyses of Vaccine Efficacy

Subgroup analyses of the second primary efficacy endpoint provide additional information about the VE for participants with and without evidence of infection prior to vaccination in specific populations enrolled, which is the endpoint considered to represent the general population who may receive the vaccine, as baseline evidence of prior infection may not be known by all people who might receive the vaccine. The results are displayed below in Table 8. The VE point estimates for the subgroup analyses were comparable to results for the first primary efficacy endpoint.

VE point estimates were uniformly high across the subgroups examined with the exception of participants identifying as multiracial and participants with evidence of prior SARS-CoV-2 infection at enrollment, for which too few COVID-19 cases occurred to interpret efficacy data for these subgroups. Additionally, the numbers of participants and cases in some other specific subgroups, such as the adolescent age group and racial subgroups, limits the interpretability of the VE results because of the wide credible intervals, but are displayed for completeness.

Table 8: Subgroup Analyses of Second Primary Endpoint: First COVID-19 Occurrence From 7 Days After Dose 2, by Subgroup, Participants With and Without Evidence of Infection Prior to 7 Days After Dose 2, Evaluable Efficacy (7 Days) Population

[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
[d] n2 = Number of participants at risk for the endpoint.
[e] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.
[f] At risk is defined as having at least one of the Charlson comorbidity index (Appendix B, page 52) category or obesity (BMI ≥30 kg/m^2).
[g] Obese is defined as BMI ≥30 kg/m^2.
[h] Positive N-binding antibody result at Visit 1, positive NAAT result at Visit 1, or medical history of COVID-19.
[i] Negative N-binding antibody result at Visit 1, negative NAAT result at Visit 1, and no medical history of COVID-19.

The demographics of the participants with confirmed COVID-19 cases contributing to the primary efficacy analysis are displayed below in Table 9.

Table 9. Demographic Characteristics, Participants With Protocol Defined Case (Without Evidence of Infection Prior to 7 Days After Dose 2)

Characteristic	BNT162b2 (N[a]=8) n[b] (%)	Placebo (N[a]=162) n[b] (%)	Total (N[a]=170) n[b] (%)

Comorbidity: Obesity	3 (37.5)	67 (41.4)	70 (41.2)

[a] N = number of participants in the specified group, or the total sample. This value is the denominator for the percentage calculations.
[b] n = Number of participants with the specified characteristic.
[c] Number of participants who have 1 or more comorbidities that increase the risk of severe COVID-19 disease: defined as patients who had at least one of the Charlson comorbidity index (Appendix B, page 52) category or obesity only (BMI ≥30 kg/m²).

Only 3% of participants had evidence of prior infection at study enrollment, and additional analyses showed that very few COVID-19 cases occurred in these participants over the course of the entire study (9 in the placebo group and 10 in the BNT162b2 group, only 1 of which occurred 7 days or more after completion of the vaccination regimen – data not shown). The placebo group attack rate from enrollment to the November 14, 2020, data cut-off date was 1.3% both for participants without evidence of prior infection at enrollment (259 cases in 19,818 participants) and for participants with evidence of prior infection at enrollment (9 cases in 670 participants). While limited, these data do suggest that previously infected individuals can be at risk of COVID-19 (i.e., reinfection) and could benefit from vaccination.

Additional analyses of the first primary efficacy endpoint were conducted to evaluate the vaccine efficacy, by comorbidity status. VE point estimates were uniformly high across the comorbidities examined, though for some interpretation of the results is limited by small numbers of participants and/or cases.

Table 10. Vaccine Efficacy: First COVID-19 Occurrence From 7 Days After Dose 2, by Comorbidity Status, Among Participants Without Evidence of Infection Prior to 7 Days After Dose 2, Evaluable Efficacy (7 Days) Population

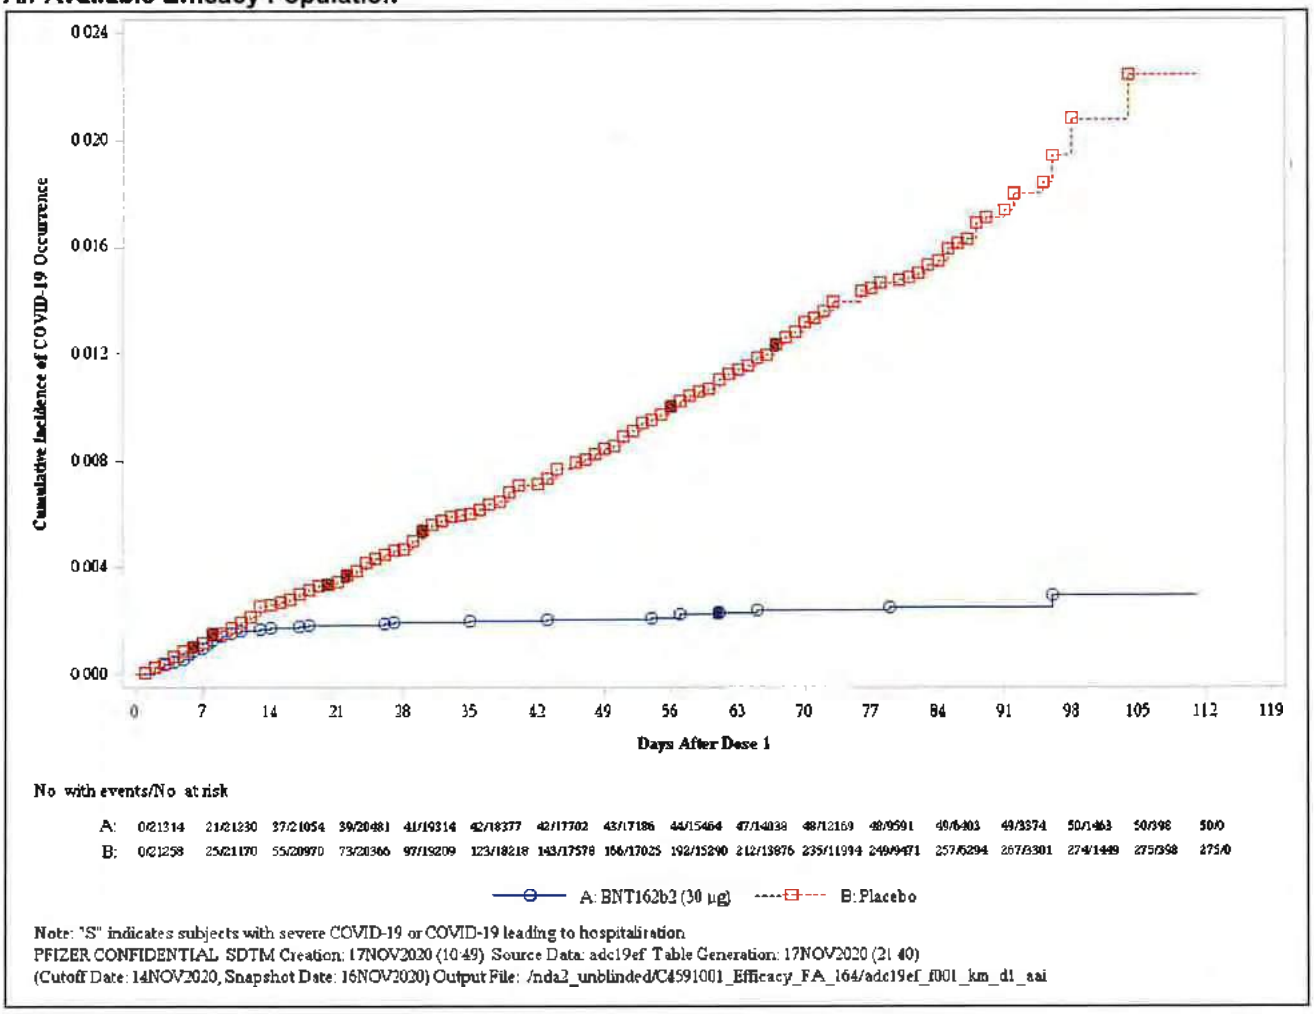
Abbreviations: N-binding = SARS-CoV-2 nucleoprotein–binding; NAAT = nucleic acid amplification test; SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2; VE = vaccine efficacy.
Note: Participants who had no serological or virological evidence (prior to 7 days after receipt of the last dose) of past SARS-CoV-2 infection (i.e., N-binding antibody [serum] negative at Visit 1 and SARS-CoV-2 not detected by NAAT [nasal swab] at Visits 1 and 2), and had negative NAAT (nasal swab) at any unscheduled visit prior to 7 days after Dose 2 were included in the analysis.
[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 days after Dose 2 to the end of the surveillance period.
[d] n2 = Number of participants at risk for the endpoint.
[e] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted for surveillance time.
[f] Subject who had 1 or more comorbidities that increase the risk of severe COVID-19 disease: defined as participants who had at least one of the Charlson comorbidity index (Appendix B, page 52) category or BMI ≥30 kg/m2.

Cumulative Incidence Curves

Based on the cumulative incidence curve for the all-available efficacy population after Dose 1, (Figure 2), COVID-19 disease onset appears to occur similarly for both BNT162b2 and placebo groups until approximately 14 days after Dose 1, at which time point, the curves diverge, with more cases accumulating in the placebo group than in the BNT162b2 group, and there does not appear to be evidence of waning protection during the follow-up time of approximately 2 months following the second dose that is being evaluated at this point in time.

Figure 2. Cumulative Incidence Curves for the First COVID-19 Occurrence After Dose 1, Dose 1 All-Available Efficacy Population



Secondary Efficacy Analyses

The secondary efficacy endpoints evaluate the VE of BNT162b2 for the prevention of COVID-19 disease from 14 days after Dose 2 and based on the CDC's definition of COVID-19 disease from 7 and 14 days after Dose 2. The case splits and VE for each of these secondary efficacy endpoints were each similar to the primary efficacy endpoints described above.

Severe COVID-19 Cases

In the final analysis of the evaluable efficacy population (7 days), four participants had severe COVID-19 disease at least 7 days after Dose 2 (one subject who received BNT162b2 and three participants who received placebo). The vaccine recipient who had severe COVID-19 disease met the severe case definition because oxygen saturation at the COVID-19 illness visit was 93% on room air. The subject was not hospitalized, did not seek further medical care, and did not have risk factors for severe disease. The three placebo recipients who had severe COVID-19 disease met the severe case definition for the following reasons: one subject had an oxygen saturation of 92% on room air without other severe disease criteria, one subject was

hospitalized for noninvasive positive pressure ventilation with bilateral pneumonia, and one subject had an oxygen saturation of 92% and ICU admission for heart block. One of these placebo recipients with severe disease also had a body mass index > 30 kg/m^2 as a risk factor, while the other two participants did not have any risk factors for severe disease. The vaccine efficacy of this secondary efficacy endpoint is shown in Table 11.

Table 11. First Severe COVID-19 Occurrence from 7 Days after Dose 2 - Evaluable Efficacy Population

Secondary Efficacy Endpoint	BNT162b2 N[a]=18198 Cases n1[b] Surveillance Time[c] (n2[d])	Placebo N[a]=18325 Cases n1[b] Surveillance Time[c] (n2[d])	Vaccine Efficacy % (95% CI)	Met Predefined Success Criterion*
First severe COVID-19 occurrence from 7 days after Dose 2 in participants without evidence of prior SARS-CoV-2 infection	1 2.215 (17411)	3 2.232 (17511)	66.4 (-124.8, 96.3)[e]	No

*Success criterion: the posterior probability that true vaccine efficacy > 30% conditioning on the available data is >98.6% at the final analysis.
[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 or 14 days after Dose 2 to the end of the surveillance period depending on specified endpoint.
[d] n2 = Number of participants at risk for the endpoint.
[e] Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time.
[f] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.

In the all-available efficacy population, ten participants had severe COVID-19 disease after Dose 1 (one subject who received BNT162b2 and nine participants who received placebo). Five of the remaining six placebo recipients who had severe COVID-19 disease were hospitalized, two of whom were admitted to an intensive care unit. Five of these remaining six placebo recipients who had severe disease had at least one risk factor for severe disease. The total number of severe cases is small, which limits the overall conclusions that can be drawn; however, the case split does suggest protection from severe COVID-19 disease.

Table 12. First Severe COVID-19 Occurrence After Dose 1 – Dose 1 All-Available Efficacy Population

Secondary Efficacy Endpoint	BNT162b2 N[a]=21669 Cases n1[b] Surveillance Time[c] (n2[d])	Placebo N[a]=21686 Cases n1[b] Surveillance Time[c] (n2[d])	Vaccine Efficacy % (95% CI)
First severe case occurrence after Dose 1	1 4.021 (21314)	9 4.006 (21259)	88.9 (20.1, 99.7)[f]
After Dose 1 to before Dose 2	0	4	100.0 (-51.5, 100.0)
Dose 2 to 7 days after Dose 2	0	1	100.0 (-3800.0, 100.0)
≥7 Days after Dose 2	1	4	75.0 (-152.6, 99.5)

[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 or 14 days after Dose 2 to the end of the surveillance period depending on specified endpoint.
[d] n2 = Number of participants at risk for the endpoint.
[e] Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time.
[f] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.

Additional Efficacy Analyses

Additional analyses of the first primary efficacy endpoint were conducted to evaluate the all-available efficacy population, for all participants regardless of evidence of prior infection through 7 days after Dose 2 (Table 13).

Table 13. Primary Efficacy Endpoint –All-Available Efficacy Population

Efficacy Endpoint	BNT162b2 N[a]=21669 Cases n1[b] Surveillance Time[c] (n2[d])	Placebo N[a]=21686 Cases n1[b] Surveillance Time[c] (n2[d])	Vaccine Efficacy % (95% CI)
First COVID-19 occurrence after	50	275	82.0
Dose 1 – Dose 1	4.015 (21314)	3.982 (21258)	(75.6, 86.9)[f]
After Dose 1 to before Dose 2	39	82	52.4 (29.5, 68.4)
Dose 2 to 7 days after Dose 2	2	21	90.5 (61, 98.9)
≥7 Days after Dose 2	9	172	94.8 (89.8, 97.6)

[a] N = number of participants in the specified group.
[b] n1 = Number of participants meeting the endpoint definition.
[c] Total surveillance time in 1000 person-years for the given endpoint across all participants within each group at risk for the endpoint. Time period for COVID-19 case accrual is from 7 or 14 days after Dose 2 to the end of the surveillance period depending on specified endpoint.
[d] n2 = Number of participants at risk for the endpoint.
[e] Credible interval for VE was calculated using a beta-binomial model with prior beta (0.700102, 1) adjusted for surveillance time.
[f] Confidence interval (CI) for VE is derived based on the Clopper and Pearson method adjusted to the surveillance time.

VE in participants in the all-available efficacy population was similar to results in the evaluable efficacy population. The VE for the prevention of COVID-19 disease after Dose 1 is 82%, in the all-available efficacy population. Based on the number of cases accumulated after Dose 1 and before Dose 2, there does seem to be some protection against COVID-19 disease following one dose; however, these data do not provide information about longer term protection beyond 21 days after a single dose.

Efficacy Summary

The data submitted in this EUA request were consistent with the recommendations set forth in the FDA Guidance on Emergency Use Authorization for Vaccines to Prevent COVID-19 and met the prespecified success criteria established in the protocol. In the planned interim and final analyses, vaccine efficacy after 7 days post Dose 2 was 95%, (95% CI 90.3; 97.6) in participants without prior evidence of SARS-CoV-2 infection and >94% in the group of participants with or without prior infection. Efficacy outcomes were consistently robust (≥93%) across demographic subgroups.

Efficacy against severe COVID-19 occurring after the first dose was 88.9% (95% CI 20.1, 99.7), with an estimated VE of 75.0% (95% CI -152.6, 99.5) (1 case in BNT162b2 group and 4 cases in placebo group) against severe COVID-19 occurring at least 7 days after Dose 2.

Among all participants (regardless of evidence of infection before or during the vaccination regimen), 50 cases of COVID-19 occurred after Dose 1 in the BNT162b2 group compared with 275 cases in the placebo group, indicating an estimated VE of 82% (95% CI: 75.6%, 86.9%) against confirmed COVID-19 occurring after Dose 1, with VE of 52.4% (95% CI: 29.5%, 68.4%) between Dose 1 and Dose 2. The efficacy observed after Dose 1 and before Dose 2, from a post-hoc analysis, cannot support a conclusion on the efficacy of a single dose of the vaccine, because the time of observation is limited by the fact that most of the participants received a

second dose after three weeks. The trial did not have a single-dose arm to make an adequate comparison.

5.2.6. Safety

Overview of Adverse Events

Table 14 below presents an overview of all adverse events in the phase 2/3 safety population. A higher proportion of vaccine recipients reported adverse events compared with placebo recipients, and this imbalance was driven by reactogenicity (solicited adverse events) reported in the 7 days following vaccination and unsolicited adverse events corresponding to reactogenicity symptoms among participants not in the reactogenicity subset (see presentation of unsolicited adverse events in a later section). Proportions of participants with serious adverse events, deaths, and withdrawals due to adverse events were balanced between treatment groups.

Table 14. Study C4591001 Safety Overview- Ages 16 years and older

Participants Experiencing at Least One:	BNT162b2 n/N (%)	Placebo n/N (%)
Immediate unsolicited AE Within 30 minutes after vaccination[a]		
Dose #1	78/18801 (0.4)	66/18785 (0.4)
Dose #2	52/18494 (0.3)	39/18470 (0.2)
Solicited injection site reaction within 7 days[b]		
Dose #1	3216/4093 (78.6)	525/4090 (12.8)
Dose #2	2748/3758 (73.1)	396/3749 (10.6)
Solicited systemic AE within 7 days[b]		
Dose #1	2421/4093 (59.1)	1922/4090 (47.0)
Dose #2	2627/3758 (69.9)	1267/3749 (33.8)
From Dose 1 through 1 month after Dose 2[a]		
Unsolicited non-serious AE	5071/18801 (27.0)	2356/18785 (12.5)
SAE	103/18801 (0.5)	81/18785 (0.4)
From Dose 1 through cutoff date (safety population)

n= number of participants with the specified reaction or AE.
[a] N: number of participants in the phase 2/3 safety population.
[b] N: number of participants in the reactogenicity subset of the phase 2/3 safety population.
[b] N: number of participants in the all-enrolled population.
Data analysis cutoff date: November 14, 2020.

Solicited Local Reactions and Systemic Adverse Events

As of the cutoff date, solicited reactogenicity data in participants 16 and 17 years of age were not collected by e-diary and are not available. Symptoms consistent with solicited reactogenicity that were reported by these participants were collected and analyzed as unsolicited adverse events and are discussed with review of those data.

Solicited Local Reactions

For each age group in the reactogenicity subset (younger: 18 to 55 years, older: >55 years) and overall (18 years and older), the median onset of local reactions in the vaccine group was 0 (day of vaccination) to 2 days after either dose and lasted a median duration between 1 and 2 days.

For both age groups, injection site pain was the most frequent solicited local adverse reaction. After dose 2, the younger age group reported any pain more frequently than the older age group (77.8% vs 66.1%) and pain characterized as moderate (27.1% vs. 18.0%); a similar pattern was observed after Dose 1. Injection site redness and swelling after each dose were generally similar for both age groups.

Data analysis cutoff date: November 14, 2020.

Solicited Systemic AEs

For each age group in the reactogenicity subset (younger: 18 to 55 years, older: >55 years) and overall (18 years and older), the median onset of systemic AEs in the vaccine group in general was 1 to 2 days after either dose and lasted a median duration of 1 day.

The frequency and severity of systemic AEs were higher in the younger than the older age groups. Within each age group, the frequency and severity of systemic AEs was higher after Dose 2 than Dose 1, except for vomiting and diarrhea, which was generally similar regardless of dose. For both age groups, fatigue, headache and new/worsened muscle pain were most common.

Unsolicited (non-serious) AEs

A higher frequency of unsolicited, non-serious adverse events was reported in the vaccine group compared to placebo group and was primarily attributed to local reactions and systemic adverse events in subjects not in the reactogenicity subset and are consistent with solicited reactions/events reported by reactogenicity subset participants during the first 7 days following vaccination. Table 19 below presents unsolicited adverse events reported by at least 1% of participants in any treatment group for the phase 2/3 safety population.

Reports of lymphadenopathy were imbalanced with notably more cases in the vaccine group (64) vs. the placebo group (6), which is plausibly related to vaccination. Bell's palsy was reported by four vaccine participants and none in the placebo group. These cases occurred at 3, 9, 37, and 48 days after vaccination. One case (onset at 3 days postvaccination) was reported as resolved with sequelae within three days after onset, and the other three were reported as continuing or resolving as of the November 14, 2020 data cut-off with ongoing durations of 10, 15, and 21 days, respectively. The observed frequency of reported Bell's palsy in the vaccine group is consistent with the expected background rate in the general population, and there is no clear basis upon which to conclude a causal relationship at this time, but FDA will recommend surveillance for cases of Bell's palsy with deployment of the vaccine into larger populations. There were no other notable patterns or numerical imbalances between treatment groups for specific categories (system organ class or preferred term) of non-serious adverse events, including other neurologic, neuro-inflammatory, and thrombotic events, that would suggest a causal relationship to BNT162b2 vaccine.

FDA independently conducted standard MedDRA queries (SMQs) using FDA-developed software (MAED) to evaluate for constellations of unsolicited adverse event preferred terms that could represent various diseases and conditions, including but not limited to allergic, neurologic, inflammatory, and autoimmune conditions. The SMQs, conducted on the phase 2/3 all-enrolled safety population, revealed a slight numerical imbalance of adverse events potentially representing allergic reactions, with more participants reporting hypersensitivity-related adverse events in the vaccine group (137 [0.63%]) compared with the placebo group (111 [0.51%]). No imbalances between treatment groups were evident for any of the other SMQs evaluated.

Immediate AEs (phase 2/3 safety population)
The frequency of immediate AEs reported in the vaccine group was 0.4% after Dose 1 and <0.3% after Dose 2 and were mainly consistent with solicited reactogenicity events. In both study groups, the most frequently reported immediate AE was injection site pain (BNT162b2 vaccine 0.3%, placebo 0.2%).

Study Withdrawals due to an AE (all-enrolled population)
Of 43,448 enrolled participants, 37 (0.2%) vaccine recipients and 30 (0.1%) placebo recipients (0.1%), and no adolescents 16 to <18 years of age, withdrew from the study due to an AE. AEs in the SOC of General Disorders and Administration Site Conditions (7 vaccine, 3 placebo) was common, with injection site pain the most frequent (2 vaccine, 0 placebo).

Serious Adverse Events

Deaths

A total of six (2 vaccine, 4 placebo) of 43,448 enrolled participants (0.01%) died during the reporting period from April 29, 2020 (first participant, first visit) to November 14, 2020 (cutoff date). Both vaccine recipients were >55 years of age; one experienced a cardiac arrest 62 days after vaccination #2 and died 3 days later, and the other died from arteriosclerosis 3 days after vaccination #1. The placebo recipients died from myocardial infarction (n=1), hemorrhagic stroke (n=1) or unknown causes (n=2); three of the four deaths occurred in the older group (>55 years of age). All deaths represent events that occur in the general population of the age groups where they occurred, at a similar rate.

Non-fatal SAEs

In the all-enrolled population of (total N=43,448), the proportions of participants who reported at least 1 SAE during the time period from Dose 1 to the data cutoff date (November 14, 2020) were 0.6% in the BNT162b2 vaccine group and 0.5% in the placebo group. The most common SAEs in the vaccine group which were numerically higher than in the placebo group were appendicitis (0.04%), acute myocardial infarction (0.02%), and cerebrovascular accident (0.02%), and in the placebo arm numerically higher than in the vaccine arm were pneumonia (0.03%), atrial fibrillation (0.02%), and syncope (0.02%). Occurrence of SAEs involving system organ classes and specific preferred terms were otherwise balanced between treatment groups, including no imbalance overall in cardiovascular serious adverse events.

Appendicitis was reported as a SAE for 12 participants, and numerically higher in the vaccine group: 8 vaccine participants ([appendicitis [n=7], appendicitis perforated [n=1]) and 4 placebo participants (appendicitis [n=2], appendicitis perforated [n=1], complicated appendicitis [n=1]). All of the vaccine participants (n=8) and 2 placebo participants were younger than 65 years of age. The cases were considered unrelated to vaccination by the study investigators and occurred no more frequently than expected in the given age groups. FDA agrees that there is no clear basis upon which to suspect that this imbalance represents a vaccine-related risk.

Three SAEs reported in the BNT162 group were considered by the investigator as related to vaccine or vaccine administration: shoulder injury, ventricular arrhythmia, and lymphadenopathy. The investigator and the sponsor thought that the shoulder injury was related to vaccine administration. Two SAEs in the BNT162b2 group and none in the placebo group were considered by the investigator, but not the Sponsor, as related to study vaccination: shoulder injury (n=1), ventricular arrhythmia in a participant with known cardiac conditions (n=1), and lymphadenopathy temporally following vaccination (n=1). In FDA's opinion following review of the adverse event narratives, two of these events were considered as possibly related to vaccine: shoulder injury possibly related to vaccine administration or to the vaccine itself, and lymphadenopathy involving the axilla contralateral to the vaccine injection site. For lymphadenopathy, the event was temporally associated and biologically plausible.

Among participants 16 to 17 years of age, there was 1 participant in the vaccine group who experienced an SAE of facial bones fracture, which was not considered related to study intervention by the investigator.

Suspected COVID-19 Cases

As specified in the protocol, suspected cases of symptomatic COVID-19 that were not PCR-confirmed were not recorded as adverse events unless they met regulatory criteria for seriousness. Two serious cases of suspected but unconfirmed COVID-19 were reported, both in the vaccine group, and narratives were reviewed. In one case, a 36-year-old male with no medical comorbidities experienced fever, malaise, nausea, headache and myalgias beginning on the day of Dose 2 and was hospitalized 3 days later for further evaluation of apparent infiltrates on chest radiograph and treatment of dehydration. A nasopharyngeal PCR test for SARS-CoV-2 was negative on the day of admission, and a chest CT was reported as normal. The participant was discharged from the hospital 2 days after admission. With chest imaging findings that are difficult to reconcile, it is possible that this event represented reactogenicity following the second vaccination, a COVID-19 case with false negative test that occurred less than 7 days after completion of the vaccination series, or an unrelated infectious process. In the other case, a 66-year-old male with no medical comorbidities experienced fever, myalgias, and shortness of breath beginning 28 days post-Dose 2 and was hospitalized one day later with abnormal chest CT showing a small left-sided consolidation. He was discharged from the hospital 2 days later, and multiple nasopharyngeal PCR tests collected over a 10-day period beginning 2 days after symptom onset were negative. It is possible, though highly unlikely, that this event represents a COVID-19 case with multiple false negative tests that occurred more than 7 days after completion of the vaccination regimen, and more likely that it represents an unrelated infectious process.

Among 3410 total cases of suspected but unconfirmed COVID-19 in the overall study population, 1594 occurred in the vaccine group vs. 1816 in the placebo group. Suspected COVID-19 cases that occurred within 7 days after any vaccination were 409 in the vaccine group vs. 287 in the placebo group. It is possible that the imbalance in suspected COVID-19 cases occurring in the 7 days postvaccination represents vaccine reactogenicity with symptoms that overlap with those of COVID-19. Overall though, these data do not raise a concern that protocol-specified reporting of suspected, but unconfirmed COVID-19 cases could have masked clinically significant adverse events that would not have otherwise been detected.

Subgroup Analyses

There were no specific safety concerns identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection, and occurrence of solicited, unsolicited, and serious adverse events in these subgroups were generally consistent with the overall study population.

Pregnancies

Female study participants of childbearing potential were screened for pregnancy prior to each vaccination, with a positive test resulting in exclusion or discontinuation from study vaccination. The study is collecting outcomes for all reported pregnancies that occur after vaccination, or before vaccination and not detected by pre-vaccination screening tests. Twenty-three pregnancies were reported through the data cut-off date of November 14, 2020 (12 vaccine, 11 placebo). Study vaccination occurred prior to the last menstrual period (LMP) in 5 participants (4 vaccine, 2 placebo), within 30 days after LMP in 8 participants (4 vaccine, 6 placebo), >30 days after LMP in 1 participant (0 vaccine, 2 placebo), and date of LMP not known in 5 participants (4 vaccine, 1 placebo). Unsolicited AEs related to pregnancy include spontaneous abortion and retained products of conception, both in the placebo group. Pregnancy outcomes are otherwise

unknown at this time.

Clinical Laboratory Evaluations

Clinical laboratory tests (hematology, chemistries) were assessed in study BNT162-01 and C4591001 phase 1. The only common laboratory abnormality reported throughout the studies was transient decreases in lymphocytes 1-3 days after Dose 1, which increased in frequency with increasing dose, were mostly Grade 1-2, generally normalized at the next laboratory assessment 6-8 days after Dose 1 and did not occur after Dose 2. Among C4591001 phase 1 participants who received the 30 µg dose of BNT162b2, transient decreases in lymphocytes post-Dose 1 occurred in 5 of 12 participants 18-55 years of age and in 4 of 12 participants 65-85 years of age. These transient hematological changes were not associated with clinical symptoms.

Safety Summary

The information provided by the Sponsor was adequate for review and to make conclusions about the safety of BNT162b2 in the context of the proposed indication and population for intended use under EUA. The number of participants in the phase 2/3 safety population (N=37586; 18801 vaccine,18785 placebo) meets the expectations in FDA's Guidance on Development and Licensure of Vaccines to Prevent COVID-19 for efficacy, and the median duration of at least 2 months follow-up after completion of the 2-dose primary vaccination series meets the agency's expectations in FDA's Guidance on its Emergency Use Authorization for Vaccines to Prevent COVID-19. The all-enrolled population contained more participants >16 years of age, regardless of duration of follow-up (43448; 21720 vaccine, 21728 placebo). The demographic and baseline characteristics of the all-enrolled population and the safety population were similar. Although the overall median duration of follow-up in the all-enrolled population was less than 2 months, because the protocol was amended to include subpopulations such as individuals with HIV and adolescents, the data from both populations altogether provide a comprehensive summary of safety.

Local site reactions and systemic solicited events after vaccination were frequent and mostly mild to moderate. The most common solicited adverse reactions were injection site reactions (84.1%), fatigue (62.9%), headache (55.1%), muscle pain (38.3%), chills (31.9%), joint pain (23.6%), fever (14.2%); severe adverse reactions occurred in 0.0% to 4.6% of participants, were more frequent after Dose 2 than after Dose 1, and were generally less frequent in adults ≥55 years of age (≤2.8%) as compared to younger participants (≤4.6%). Among adverse events of special interest, which could be possibly related to vaccine, lymphadenopathy was reported in 64 participants (0.3%): 54 (0.5%) in the younger (16 to 55 years) age group; 10 (0.1%) in the older (>55 years) age group; and 6 in the placebo group. The average duration of these events was approximately 10 days, with 11 events ongoing at the time of the data cutoff. Bell's palsy was reported by four vaccine participants. From Dose 1 through 1 month after Dose 2, there were three reports of Bell's palsy in the vaccine group and none in the placebo group. This observed frequency of reported Bell's palsy is consistent with the expected background rate in the general population. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of non-serious adverse events (including other neurologic, neuro-inflammatory, and thrombotic events) that would suggest a causal relationship to BNT162b2 vaccine.

A total of six deaths occurred in the reporting period (2 deaths in the vaccine group, 4 in placebo). In the vaccine group, one participant with baseline obesity and pre-existing atherosclerosis died 3 days after Dose 1, and the other participant experienced cardiac arrest

60 days after Dose 2 and died 3 days later. Of the four deaths in the placebo arm, the cause was unknown for two of them, and the other two participants died from hemorrhagic stroke (n=1) and myocardial infarction (n=1), respectively; three deaths occurred in the older group (>55 years of age). All deaths represent events that occur in the general population of the age groups where they occurred, at a similar rate.

The frequency of non-fatal serious adverse events was low (<0.5%), without meaningful imbalances between study arms. The most common SAEs in the vaccine arm which were numerically higher than in the placebo arm were appendicitis (0.04%), acute myocardial infarction (0.02%), and cerebrovascular accident (0.02%), and in the placebo arm numerically higher than in the vaccine arm were pneumonia (0.03%), atrial fibrillation (0.02%), atrial fibrillation (0.02%) and syncope (0.02%). Appendicitis was the most common SAE in the vaccine arm. There were 12 participants with SAEs of appendicitis; 8 in the BNT162b2 group. Of the 8 total appendicitis cases in the BNT162b2 group, 6 occurred in the younger (16 to 55 years) age group and 2 occurred in the older (>55 years) age group (one of the cases in the older age group was perforated). One of the 6 participants with appendicitis in the younger age group also had a peritoneal abscess. Cases of appendicitis in the vaccine group were not more frequent than expected in the general population.

6. Sponsor's Plans for Continuing Blinded, Placebo-Controlled Follow-Up

The Sponsor plans to offer vaccination to participants ⩾16 years of age who originally received placebo and who become eligible for receipt of BNT162b2 according to local or national recommendations. The Sponsor proposes that these participants will be unblinded upon request and will have the opportunity to receive BNT162b2 as part of the study. The Sponsor also proposes that all placebo recipients ⩾16 years of age will be offered BNT162b2 after completing 6 months of follow-up after Dose 2, if they did not request and receive vaccine previously. The participants will provide consent to receive vaccination and to continue follow-up. For these participants, the Sponsor plans a total follow up period of 18 months, with one visit 1-month postvaccination and subsequent phone contacts at 1, 6, and 18 months postvaccination. Safety and efficacy monitoring during this period will include collection of AEs, SAEs, and screening and diagnosing COVID-19 cases.

7. Pharmacovigilance Activities

Pfizer submitted a Pharmacovigilance Plan (PVP) to monitor safety concerns that could be associated with Pfizer-BioNTech COVID-19 Vaccine. The Sponsor identified vaccine-associated enhanced disease including vaccine-associated enhanced respiratory disease as an important potential risk. Use in pregnancy and lactation and vaccine effectiveness are areas the Sponsor identified as missing information. In addition to the safety concerns specified by the Sponsor, FDA requested that the Sponsor update their PVP to include missing information in pediatric participants less than 16 years of age.

The Sponsor will conduct both passive and active surveillance activities for continued vaccine safety monitoring. Passive surveillance activities will include submitting spontaneous reports of the following events to the Vaccine Adverse Event Reporting System (VAERS) within 15 days:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in children and adults
- Cases of COVID-19 that result in hospitalization or death

The Sponsor will also conduct periodic aggregate review of safety data and submit periodic safety reports at monthly intervals. Each periodic safety report is required to contain descriptive information which includes:

- A narrative summary and analysis of adverse events submitted during the reporting interval, including interval and cumulative counts by age groups, special populations (e.g., pregnant women), and adverse events of special interest
- Newly identified safety concerns in the interval
- Actions taken since the last report because of adverse experiences (e.g., changes made to Vaccination Provider fact sheets, changes made to studies or studies initiated)

Sponsor studies will include completion of long-term follow-up from ongoing clinical trials as well as the following three planned active surveillance studies. Of note, the Sponsor will submit plans for a clinical study to assess safety and immunogenicity in pregnant women and has proposed active surveillance studies designed to monitor vaccination during pregnancy within populations expected to receive the vaccine under EUA.

- Study Protocol Number C4591008. The Sponsor proposes to survey 20,000 U.S. health care workers enrolled in the COVID-19 HERO registry as well as health care workers in certain participating health care facilities about adverse events of special interest, and other clinically significant events of interest after vaccination with the Pfizer-BioNTech COVID-19 Vaccine. Incidence rates of these events in this cohort will be compared to expected rates. The respondents would receive follow-up surveys for a 30-month period.
- Study Protocol Number C4591011. This study is an active safety surveillance evaluation conducted within the Department of Defense Health System Databases using data derived from electronic health records and medical service claims among covered U.S. military and their families. Rates of safety events of interest in vaccinated participants will be compared to unvaccinated comparators. The study will be conducted for 30 months.
- Study Protocol Number C4591012. This study is an active surveillance study for adverse events of special interest and other clinically significant events associated with the Pfizer-BioNTech COVID-19 Vaccine using the Veteran's Health Administration electronic medical record database. Vaccinated participants will be compared to unvaccinated participants or to recipients of seasonal influenza vaccine. The study will be conducted for 30 months.

Currently, the primary objective of all three proposed studies above is descriptive, and the list of adverse events in the studies has not been finalized. FDA will provide feedback on these studies after further review.

Reporting to VAERS and Pfizer, Inc.

Providers administering the Pfizer-BioNTech COVID-19 Vaccine must report to VAERS (as required by the National Childhood Vaccine Injury Act) and to Pfizer the following information associated with the vaccine of which they become aware:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in children and adults
- Cases of COVID-19 that result in hospitalization or death

Additional VAERS Reporting

An additional source of VAERS reports will be through a program administered by the CDC known as v-safe. V-safe is a new smartphone-based opt-in program that uses text messaging and web surveys from CDC to check in with vaccine recipients for health problems following COVID-19 vaccination. The system also will provide telephone follow-up to anyone who reports medically significant (important) adverse events. Responses indicating missed work, inability to do normal daily activities, or that the recipient received care from a doctor or other healthcare professional will trigger the VAERS Call Center to reach out to the participant and collect information for a VAERS report, if appropriate.

8. Benefit/Risk Assessment in the Context of Proposed Indication and Use Under EUA

8.1. Known Benefits

The known benefits among recipients of the proposed vaccine relative to placebo are:

- Reduction in the risk of confirmed COVID-19 occurring at least 7 days after Dose 2
- Reduction in the risk of confirmed COVID-19 after Dose 1 and before Dose 2
- Reduction in the risk of confirmed severe COVID-19 any time after Dose 1

The protocol-specified 2-dose vaccination regimen was highly effective in preventing PCR-confirmed COVID-19 occurring at least 7 days after completion of the vaccination regimen. Additional primary efficacy analyses in the all-available efficacy population, including participants who had protocol violations, showed consistency with outcomes in the primary analysis population. Efficacy findings were also consistent across various subgroups, including racial and ethnic minorities, participants aged 65 years and older, and those with one or more of the following conditions: obesity, diabetes, hypertension, and chronic cardiopulmonary diseases. While limited, available data suggest that individuals with previous SARS-CoV-2 infection can be at risk of COVID-19 (i.e., re-infection) and may benefit from vaccination.

Among participants with no evidence of COVID-19 prior to vaccination, the vaccine was effective in reducing the risk of COVID-19 and severe COVID-19 after Dose 1. Fewer severe cases were also observed in the vaccine recipients relative to recipients of placebo during the follow up period after Dose 1. The findings post Dose 1, from a post-hoc analysis, cannot be the basis to assess the potential efficacy of the vaccine when administered as a single dose because the period of observation is limited by the fact that most participants received a second dose three weeks after the first one.

8.2. Unknown Benefits/Data Gaps

Duration of protection

As the interim and final analyses have a limited length of follow-up, it is not possible to assess sustained efficacy over a period longer than 2 months.

Effectiveness in certain populations at high-risk of severe COVID-19

Although the proportion of participants at high risk of severe COVID-19 is adequate for the overall evaluation of safety in the available follow-up period, the subset of certain groups such as immunocompromised individuals (e.g., those with HIV/AIDS) is too small to evaluate efficacy outcomes.

Effectiveness in individuals previously infected with SARS-CoV-2

The primary endpoint was evaluated in individuals without prior evidence of COVID-19 disease, and very few cases of confirmed COVID-19 occurred among participants with evidence of infection prior to vaccination (although more cases occurred in the placebo group compared with the vaccine group). Therefore, available data are insufficient to make conclusions about benefit in individuals with prior SARS-CoV-2 infection. However, available data, while limited, do suggest that previously infected individuals can be at risk of COVID-19 (i.e., reinfection) and could benefit from vaccination.

Effectiveness in pediatric populations

The representation of pediatric participants in the study population is too limited to adequately evaluate efficacy in pediatric age groups younger than 16 years. No efficacy data are available from participants ages 15 years and younger. Although adolescents 16 to 17 years of age were included in the overall efficacy analysis, only one confirmed COVID-19 case was reported in this age group. However, it is biologically reasonable to extrapolate that effectiveness in ages 16 to 17 years would be similar to effectiveness in younger adults. Efficacy surveillance continued beyond November 14, 2020, and the Sponsor has represented that additional data will be provided in a BLA.

Future vaccine effectiveness as influenced by characteristics of the pandemic, changes in the virus, and/or potential effects of co-infections

The study enrollment and follow-up occurred during the period of July 27 to November 14, 2020, in various geographical locations. The evolution of the pandemic characteristics, such as increased attack rates, increased exposure of subpopulations, as well as potential changes in the virus infectivity, antigenically significant mutations to the S protein, and/or the effect of co-infections may potentially limit the generalizability of the efficacy conclusions over time. Continued evaluation of vaccine effectiveness following issuance of an EUA and/or licensure will be critical to address these uncertainties.

Vaccine effectiveness against asymptomatic infection

Data are limited to assess the effect of the vaccine against asymptomatic infection as measured by detection of the virus and/or detection of antibodies against non-vaccine antigens that would indicate infection rather than an immune response induced by the vaccine. Additional evaluations will be needed to assess the effect of the vaccine in preventing asymptomatic infection, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against long-term effects of COVID-19 disease

COVID-19 disease may have long-term effects on certain organs, and at present it is not possible to assess whether the vaccine will have an impact on specific long-term sequelae of COVID-19 disease in individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 should translate to overall prevention of COVID-19-related sequelae in vaccinated populations, though it is possible that asymptomatic infections may not be prevented as effectively as symptomatic infections and may be associated with sequelae that are either late-onset or undetected at the time of infection (e.g., myocarditis). Additional evaluations will be needed to assess the effect of the vaccine in preventing long-term effects of COVID-19, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against mortality

A larger number of individuals at high risk of COVID-19 and higher attack rates would be needed to confirm efficacy of the vaccine against mortality. However, non-COVID vaccines (e.g., influenza) that are efficacious against disease have also been shown to prevent disease-associated death.[11-14] Benefits in preventing death should be evaluated in large observational studies following authorization.

Vaccine effectiveness against transmission of SARS-CoV-2

Data are limited to assess the effect of the vaccine against transmission of SARS-CoV-2 from individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 may translate to overall prevention of transmission in populations with high enough vaccine uptake, though it is possible that if efficacy against asymptomatic infection were lower than efficacy against symptomatic infection, asymptomatic cases in combination with reduced mask-wearing and social distancing could result in significant continued transmission. Additional evaluations including data from clinical trials and from vaccine use post-authorization will be needed to assess the effect of the vaccine in preventing virus shedding and transmission, in particular in individuals with asymptomatic infection.

8.3. Known Risks

The vaccine has been shown to elicit increased local and systemic adverse reactions as compared to those in the placebo arm, usually lasting a few days. The most common solicited adverse reactions were injection site reactions (84.1%), fatigue (62.9%), headache (55.1%), muscle pain (38.3%), chills (31.9%), joint pain (23.6%), fever (14.2%). Adverse reactions characterized as reactogenicity were generally mild to moderate. The number of subjects reporting hypersensitivity-related adverse events was numerically higher in the vaccine group compared with the placebo group (137 [0.63%] vs. 111 [0.51%]). Severe adverse reactions occurred in 0.0-4.6% of participants, were more frequent after Dose 2 than after Dose 1 and were generally less frequent in older adults (>55 years of age) (≤2.8%) as compared to younger participants (≤4.6%). Among reported unsolicited adverse events, lymphadenopathy occurred much more frequently in the vaccine group than the placebo group and is plausibly related to vaccination.

Serious adverse events, while uncommon (<1.0%), represented medical events that occur in the general population at similar frequency as observed in the study. Three SAEs in the BNT162b2 group were considered related by the investigator, but not the Sponsor, as related to study vaccination: shoulder injury (n=1), ventricular arrhythmia in a participant with known cardiac conditions (n=1), and lymphadenopathy temporally related following vaccination (n=1). We considered two of the events as possibly related to vaccine: the shoulder injury possibly due to vaccine administration or the vaccine itself and lymphadenopathy. Lymphadenopathy was temporally associated and biologically plausible.

No specific safety concerns were identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection. Although participants 16 to 17 years of age were enrolled in the phase 3 trial, safety data for this age group is limited. However, available data are consistent with the safety profile in the adult population, and it is biologically reasonable to extrapolate the greater safety experience in adults, in particular younger adults, to the oldest pediatric age group of 16 to 17 years.

8.4. Unknown Risks/Data Gaps

Safety in certain subpopulations

There are currently insufficient data to make conclusions about the safety of the vaccine in subpopulations such as children less than 16 years of age, pregnant and lactating individuals, and immunocompromised individuals.

Adverse reactions that are very uncommon or that require longer follow-up to be detected

Following authorization of the vaccine, use in large numbers of individuals may reveal additional, potentially less frequent and/or more serious adverse events not detected in the trial safety population of nearly 44,000 participants over the period of follow up at this time. Active and passive safety surveillance will continue during the post authorization period to detect new safety signals.

A numerically greater number of appendicitis cases occurred in the vaccine group but occurred no more frequently than expected in the given age groups and do not raise a clear concern at this time for a causal relationship to study vaccination. Although the safety database revealed an imbalance of cases of Bell's palsy (4 in the vaccine group and none in the placebo group), causal relationship is less certain because the number of cases was small and not more frequent than expected in the general population. Further signal detection efforts for these adverse events will be informative with more widespread use of the vaccine.

Vaccine-enhanced disease

Available data do not indicate a risk of vaccine-enhanced disease, and conversely suggest effectiveness against severe disease within the available follow-up period. However, risk of vaccine-enhanced disease over time, potentially associated with waning immunity, remains unknown and needs to be evaluated further in ongoing clinical trials and in observational studies that could be conducted following authorization and/or licensure.

10. Appendix A. Study BNT162-01

Design

Study BNT162-01 is an ongoing, first-in-human, phase 1 dose-level finding study conducted in Germany to evaluate the safety and immunogenicity of several different candidate vaccines, including BNT162b2. Twelve adults 18 to 55 years of age received 30ug BNT162b2.

Secondary and exploratory objectives were specified to describe the immune response, measured by functional antibody titer, antibody binding assay, and cell-mediated immune responses (cytokines associated with Th1 and Th2 responses to assess for the induction of a balanced versus Th1 or Th2 dominant immune response) at baseline and various time points after vaccination, specifically 7 days post Dose 2. Adverse event monitoring was the same as in study C4591001.

Results

No SAEs were reported in the BNT162-01 safety database included in the EUA submission, and the safety profile for BNT162b2 in this study was similar to that in the much larger study, C4591001.

Evaluable ELISPOT data were available from 39 participants across dose levels of BNT162b2 (data cutoff date was 17 September 2020). Evaluable intracellular cytokine staining and FACS data were available from 36 participants across dose levels of BNT162b2 (cutoff date was 04 September 2020). Data for serology results for serum neutralizing titers were available for 45 participants across dose levels of BNT162b2 (data cutoff date was 18 September 2020). Most participants who received both doses of BNT162b2 had evidence of SARS-CoV-2 S protein-specific CD4+ (39/39, 100%) and CD8+ (35/39, 89.7%) T cell responses. These T cell responses were directed against different parts of the antigen, including epitopes in the RBD, indicating the induction of multi-epitope responses by BNT162b2. Functionality and polarization of S-specific BNT162b2-induced SARS-CoV-2 T cells were assessed by intracellular accumulation of cytokines IFNγ, IL-2, and IL-4 measured after stimulation with overlapping peptide pools representing the full-length sequence of the whole SARS-CoV-2 S protein. For benchmarking, PBMC fractions from 15 convalescent patients with virologically confirmed COVID-19 were used. The Th1 polarization of the T helper response was characterized by the IFNγ and IL-2 production, and only minor IL-4, production upon antigen-specific (SARS-CoV-2 S protein peptide pools) re-stimulation. The SARS-CoV-2 neutralizing geometric mean titer (GMTs) increased over baseline after Dose 1, with a boost effect after Dose 2 that was most pronounced at the 30 µg dose level.

Thus, the immunogenicity results from Study BNT162-01 showed evidence of antibody-mediated SARS-CoV-2 neutralization and a Th1 polarization in the cell-mediated cellular immune responses in healthy adults 18 to 55 years of age, which supports the final dose selection and prospect of benefit for the enrollment of larger numbers of participants in Study C4591001.

11. Appendix B. Charlson Comorbidity Index

This index is based on a list of 19 conditions identified from diagnoses in hospital and physician data. Each condition is assigned a weight from 1 to 6. The index score is the sum of the weights for all identified conditions (Charlson et al., 1987). An index score of 0 indicates no comorbid conditions, while higher scores indicate a greater level of comorbidity.

Charlson Index Diagnoses: Cancer, Chronic Pulmonary Disease, Diabetes without Complications, Congestive Heart Failure, Cerebrovascular Disease, Dementia, Renal Disease, Peripheral Vascular Disease, Myocardial Infarction, Diabetes with Complications, Paraplegia and Hemiplegia, Connective Tissue Disease-Rheumatic Disease, Peptic Ulcer Disease, Mild Liver Disease, Metastatic Carcinoma, Moderate or Severe Liver Disease, HIV/AIDS.

1. Executive Summary

On November 30, 2020, ModernaTX (the Sponsor) submitted an Emergency Use Authorization (EUA) request to FDA for an investigational COVID-19 vaccine (mRNA-1273) intended to prevent COVID-19 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The vaccine is based on the SARS-CoV-2 spike glycoprotein (S) antigen encoded by RNA and formulated in lipid nanoparticles (LNPs). The proposed use under an EUA is for active immunization for the prevention of COVID-19 caused by SARS-CoV-2 in individuals 18 years of age and older. The proposed dosing regimen is 2 doses, 100 µg each, administered 1 month apart.

The EUA request includes safety and efficacy data from an ongoing Phase 3 randomized, double-blinded and placebo-controlled trial of mRNA-1273 in approximately 30,400 participants. The primary efficacy endpoint is the reduction of incidence of COVID-19 among participants without evidence of SARS-CoV-2 infection before the first dose of vaccine in the period after 14 days post-dose 2. In an interim analysis conducted using a data cutoff of November 7, 2020, a total of 27,817 participants randomized 1:1 to vaccine or placebo with a median 7 weeks of follow-up post-dose 2 were included in the per-protocol efficacy analysis population of participants without evidence of SARS-CoV-2 infection prior to vaccination. Efficacy in preventing confirmed COVID-19 occurring at least 14 days after the second dose of vaccine was 94.5.0% (95% CI 86.5%, 97.8%) with 5 COVID-19 cases in the vaccine group and 90 COVID-19 cases in the placebo group. Subgroup analyses of the primary efficacy endpoint showed similar efficacy point estimates across age groups, genders, racial and ethnic groups, and participants with medical comorbidities associated with high risk of severe COVID-19. Secondary efficacy analyses suggested benefit of the vaccine in preventing severe COVID-19 (11 protocol-defined severe COVID-19 cases in the placebo group vs. 0 cases in the vaccine group), in preventing COVID-19 following the first dose, and in preventing COVID-19 in individuals with prior SARS-CoV-2 infection, although available data for some of these outcomes did not allow for firm conclusions. Efficacy data from the final scheduled analysis of the primary efficacy endpoint (data cutoff of November 21, 2020, with a median follow-up of >2 months post-dose 2) demonstrated a VE of 94.1% (95% CI 89.3%, 96.8%), with 11 COVID-19 cases in the vaccine group and 185 COVID-19 cases in the placebo group and was consistent with results obtained from the interim analysis. The VE in this analysis when stratified by age group was 95.6% (95% CI: 90.6%, 97.9%) for participants 18 to <65 years of age and 86.4% (95% CI: 61.4%, 95.5%) for participants ⩾65 years of age. A final secondary efficacy analysis also supported efficacy against protocol-defined severe COVID-19, with 30 cases in the placebo group vs. 0 cases in the vaccine group.

Safety data from a November 11, 2020 interim analysis of approximately 30,350 participants ≥18 years of age randomized 1:1 to vaccine or placebo with a median of 7 weeks of follow-up after the second dose supported a favorable safety profile, with no specific safety concerns identified that would preclude issuance of an EUA. These safety data are the primary basis of FDA's safety review. On December 7, 2020, the Sponsor submitted additional follow-up data from these participants with a cutoff of November 25, 2020, which represents a median of 9 weeks (>2 months) of follow-up post-dose 2. Key safety data from this later submission, including death, other serious adverse events, and unsolicited adverse events of interest were independently verified and confirmed not to change the safety conclusions from the interim safety analysis.

The most common solicited adverse reactions associated with mRNA-1273 were injection site pain (91.6%), fatigue (68.5%), headache (63.0%), muscle pain (59.6%), joint pain (44.8%), and

chills (43.4%); severe adverse reactions occurred in 0.2% to 9.7% of participants, were more frequent after dose 2 than after dose 1, and were generally less frequent in participants ≥65 years of age as compared to younger participants. Among unsolicited adverse events of clinical interest, which could be possibly related to vaccine, using the November 25, 2020 data cutoff, lymphadenopathy was reported as an unsolicited event in 173 participants (1.1%) in the vaccine group and 95 participants (0.63%) in the placebo group. Lymphadenopathy (axillary swelling and tenderness of the vaccination arm) was a solicited adverse reaction observed after any dose in 21.4% of vaccine recipients <65 years of age and in 12.4% of vaccine recipients ≥65 years of age, as compared with 7.5% and 5.8% of placebo recipients in those age groups, respectively. There was a numerical imbalance in hypersensitivity adverse events across study groups, with 1.5% of vaccine recipients and 1.1% of placebo recipients reporting such events in the safety population. There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine. Throughout the safety follow-up period to date, there were three reports of facial paralysis (Bell's palsy) in the vaccine group and one in the placebo group. Currently available information is insufficient to determine a causal relationship with the vaccine. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of adverse events (including other neurologic, neuro-inflammatory, and thrombotic events) that would suggest a causal relationship to mRNA-1273.

The frequency of serious adverse events was low (1.0% in the mRNA-1273 arm and 1.0% in the placebo arm), without meaningful imbalances between study arms. The most common SAEs in the vaccine group which were numerically higher than the placebo group were myocardial infarction (0.03%), cholecystitis (0.02%), and nephrolithiasis (0.02%), although the small numbers of cases of these events do not suggest a causal relationship. The most common SAEs in the placebo arm which were numerically higher than the vaccine arm, aside from COVID-19 (0.1%), were pneumonia (0.05%) and pulmonary embolism (0.03%).

With the exception of more frequent, generally mild to moderate reactogenicity in participants <65 years of age, the safety profile of mRNA-1273 was generally similar across age groups, genders, ethnic and racial groups, participants with or without medical comorbidities, and participants with or without evidence of prior SARS-CoV-2 infection at enrollment.

This meeting of the Vaccines and Related Biological Products Advisory Committee (VRBPAC) is being convened to discuss and provide recommendations on whether, based on the totality of scientific evidence available, the benefits of the mRNA-1273 COVID-19 Vaccine outweigh its risks for use in individuals 18 years of age and older. The committee will also discuss what additional studies should be conducted by the vaccine manufacturer following issuance of the EUA to gather further data on the safety and effectiveness of this vaccine.

2. Background

2.1 SARS-CoV-2 Pandemic

The SARS-CoV-2 pandemic presents an extraordinary challenge to global health and, as of December 11, 2020, has caused more than 71 million cases of COVID-19 and claimed the lives of more than 1.6 million people worldwide. In the United States, more than 16 million cases have been reported to the Centers for Disease Control and Prevention (CDC), with over 296,000 deaths. Confirmed cases and mortality continue to rise globally. On January 31, 2020, the U.S. Secretary of Health and Human Services (HHS) declared a public health emergency related to COVID-19 and mobilized the Operating Divisions of HHS. Following the World Health Organization's declaration of the novel coronavirus pandemic on March 11, 2020, the U.S.

President declared a national emergency in response to COVID-19 on March 13, 2020. Vaccines to protect against COVID-19 are critical to mitigate the current SARS-CoV-2 pandemic and to prevent future disease outbreaks.

SARS-CoV-2 is a novel, zoonotic coronavirus that emerged in late 2019 in patients with pneumonia of unknown cause.[1] The virus was named SARS-CoV-2 because of its similarity to the coronavirus responsible for severe acute respiratory syndrome (SARS-CoV, a lineage B betacoronavirus).[2] SARS-CoV-2 is an enveloped, positive sense, single stranded RNA virus sharing more than 70% of its sequence with SARS-CoV, and ~50% with the coronavirus responsible for Middle Eastern respiratory syndrome (MERS-CoV).[3] The SARS-CoV-2 spike glycoprotein (S), which is the main target for neutralizing antibodies, binds to its receptor human angiotensin converting enzyme 2 (hACE2) to initiate infection.[4] SARS-CoV-2 is the cause of COVID-19, an infectious disease with respiratory and systemic manifestations. Disease symptoms vary, with many persons presenting with asymptomatic or mild disease and some progressing to severe respiratory tract disease including pneumonia and acute respiratory distress syndrome (ARDS), leading to multiorgan failure and death.

In an attempt to prevent the spread of disease and to control the pandemic, numerous COVID-19 vaccine candidates are in development. These vaccines are based on different platforms including mRNA and DNA technologies and include viral vectored, subunit, inactivated, and live-attenuated vaccines. Most COVID-19 candidate vaccines express the spike protein or parts of the spike protein, i.e., the receptor binding domain, as the immunogenic determinant.

2.2 EUA Request for the Moderna COVID-19 Vaccine mRNA-1273

ModernaTX, Inc. (Sponsor) is developing a vaccine to prevent COVID-19 that is based on the pre-fusion stabilized SARS-CoV-2 spike glycoprotein (S) antigen encoded by mRNA and formulated in a lipid nanoparticle (LNP). The Moderna COVID-19 Vaccine (also referred to as mRNA-1273) is a 2-dose series of 100-µg intramuscular injections administered 1 month apart. The vaccine is supplied as a multi-dose vial (10 doses) containing a frozen suspension -25° to -15°C) of mRNA-1273 that must be thawed prior to administration. The vaccine does not contain a preservative.

A Phase 3 randomized and placebo-controlled trial using mRNA-1273 in approximately 30,000 participants is currently ongoing to evaluate the vaccine's safety and efficacy. A prespecified interim efficacy analysis from 27,817 participants using a data cutoff date of November 7, 2020, demonstrated vaccine efficacy (VE) of 94.5% (95% CI: 86.5%, 97.8%) for the prevention of symptomatic confirmed COVID-19 occurring at least 14 days after the second dose. At the time of this interim analysis, the median efficacy follow-up was 7 weeks post completion of the 2-dose series. Safety data from a November 11, 2020, interim analysis with a median of 7 weeks follow-up after the second dose of vaccine were reported to demonstrate an acceptable tolerability profile with no significant safety concerns. On November 30, 2020, ModernaTX submitted an EUA request to FDA, based on the interim analyses described above, for use of mRNA-1273 to prevent COVID-19 caused by SARS-CoV-2 in individuals 18 years of age and older.

On December 7, 2020, the Sponsor submitted an amendment to the EUA request with additional accrued safety data on all participants with a median of 2 months (9 weeks) follow-up after the second dose, using a data cutoff date of November 25, 2020, and data from the prespecified final efficacy analysis using a data cutoff of November 21, 2020, which met the median follow-up of 2 months after dose 2 and demonstrated vaccine efficacy of 94.1% (95%

CI: 89.3%, 96.8%) for the prevention of symptomatic confirmed COVID-19 occurring at least 14 days after the second dose. Although the complete datasets and analyses from the primary efficacy analysis and associated safety analyses submitted on December 7, 2020, have not been independently verified by the FDA to the same extent as the data for the interim efficacy analyses and associated safety analyses submitted on November 30, 2020, based on comprehensive independent review of the data from the interim analysis, and the consistency of findings across the two analysis time points, FDA considers that the totality of available data are sufficient to support an evaluation of this product for EUA.

2.3 U.S. Requirements to Support Issuance of an EUA for a Biological Product

Based on the declaration by the Secretary of HHS that the COVID-19 pandemic constitutes a public health emergency with a significant potential to affect national security or the health and security of United States citizens living abroad, FDA may issue an EUA after determining that certain statutory requirements are met (section 564 of the Federal Food, Drug, and Cosmetic Act (FD&C Act) (21 U.S.C. 360bbb-3)).[5]

- The chemical, biological, radiological, or nuclear (CBRN) agent referred to in the March 27, 2020 EUA declaration by the Secretary of HHS (SARS-CoV-2) can cause a serious or life-threatening disease or condition.
- Based on the totality of scientific evidence available, including data from adequate and well-controlled trials, if available, it is reasonable to believe that the product may be effective to prevent, diagnose, or treat such serious or life-threatening disease or condition that can be caused by SARS-CoV-2, or to mitigate a serious or life-threatening disease or condition caused by an FDA-regulated product used to diagnose, treat, or prevent a disease or condition caused by SARS-CoV-2.
- The known and potential benefits of the product, when used to diagnose, prevent, or treat the identified serious or life-threatening disease or condition, outweigh the known and potential risks of the product.
- There is no adequate, approved, and available alternative to the product for diagnosing, preventing, or treating the disease or condition.

If these criteria are met, under an EUA, FDA can allow unapproved medical products (or unapproved uses of approved medical products) to be used in an emergency to diagnose, treat, or prevent serious or life-threatening diseases or conditions caused by threat agents. FDA has been providing regulatory advice to COVID-19 vaccine manufacturers regarding the data needed to determine that a vaccine's benefit outweigh its risks. This includes demonstrating that manufacturing information ensures product quality and consistency along with data from at least one phase 3 clinical trial demonstrating a vaccine's safety and efficacy in a clear and compelling manner.

In the event an EUA is issued for this product, it would still be considered unapproved and would continue under further investigation (under an Investigational New Drug Application). Licensure of a COVID-19 vaccine will be based on review of additional manufacturing, efficacy, and safety data, providing greater assurance of the comparability of licensed product to product tested in the clinical trials, greater assurance of safety based on larger numbers of vaccine recipients who have been followed for a longer period of time, and additional information about efficacy that addresses, among other questions, the potential for waning of protection over time.

2.4 Alternatives for Prevention of COVID-19

No vaccine or other medical product is FDA approved for prevention of COVID-19. On December 11, 2020, FDA issued an EUA for the Pfizer-BioNTech COVID-19 vaccine for active immunization for prevention of COVID-19 due to SARS-CoV-2 in individuals 16 years of age and older. However, the Pfizer-BioNTech COVID-19 vaccine is not an approved product, and furthermore is not available in quantity sufficient to vaccinate all persons in the U.S. for whom the vaccine is authorized for use. On October 22, 2020, FDA approved remdesivir for use in adult and pediatric patients 12 years of age and older and weighing at least 40 kilograms for the treatment of COVID-19 requiring hospitalization. Several other therapies are currently available under emergency use authorization, but not FDA approved, for treatment of COVID-19. Thus, there is currently no adequate, approved, and available alternative for prevention of COVID-19.

2.5 Applicable Guidance for Industry

Risk and benefit considerations are unique for COVID-19 vaccines, given that an EUA may be requested to allow for a vaccine's rapid and widespread deployment for administration to millions of individuals, including healthy people. FDA published in October 2020 guidance for industry entitled "Emergency Use Authorization for Vaccines to Prevent COVID-19" describing FDA's current recommendations regarding the manufacturing, nonclinical, and clinical data and information needed under section 564 of the FD&C Act to support the issuance of an EUA for an investigational vaccine to prevent COVID-19, including a discussion of FDA's current thinking regarding the circumstances under which an EUA for a COVID-19 vaccine would be appropriate.[6]

2.6 Safety and Effectiveness Information Needed to Support an EUA

Effectiveness data

Issuance of an EUA requires a determination that the known and potential benefits of the vaccine outweigh the known and potential risks. For a preventive COVID-19 vaccine to be potentially administered to millions of individuals, including healthy individuals, data adequate to inform an assessment of the vaccine's benefits and risks and support issuance of an EUA would include meeting the prespecified success criteria for the study's primary efficacy endpoint, as described in the guidance for industry entitled "Development and Licensure of Vaccines to Prevent COVID-19" (i.e., a point estimate for a placebo-controlled efficacy trial of at least 50%, with a lower bound of the appropriately alpha-adjusted confidence interval around the primary efficacy endpoint point estimate of >30%).[7]

Safety data

An EUA request for a COVID-19 vaccine should include all safety data accumulated from studies conducted with the vaccine, with data from Phase 1 and 2 focused on serious adverse events, adverse events of special interest, and cases of severe COVID-19 among study participants. Phase 3 safety data should include characterization of reactogenicity (common and expected adverse reactions shortly following vaccination) in a sufficient number of participants from relevant age groups and should include a high proportion of enrolled participants (numbering well over 3,000) followed for serious adverse events and adverse events of special interest for at least one month after completion of the full vaccination regimen. The Phase 1 and 2 safety data likely will be of a longer duration than the available safety data from the Phase 3 trial at the time of submission of an EUA request and thus, are intended to complement the available data from safety follow-up from ongoing Phase 3 studies.

Phase 3 Follow-up

Data from Phase 3 studies should include a median follow-up duration of at least 2 months after completion of the full vaccination regimen to help provide adequate information to assess a vaccine's benefit-risk profile. From a safety perspective, a 2-month median follow-up following completion of the full vaccination regimen will allow identification of potential adverse events that were not apparent in the immediate postvaccination period. Adverse events considered plausibly linked to vaccination generally start within 6 weeks of vaccine receipt.[8] Therefore, a 2-month follow-up period may allow for identification of potential immune-mediated adverse events that began within 6 weeks of vaccination. From the perspective of vaccine efficacy, it is important to assess whether protection mediated by early responses has not started to wane. A 2-month median follow-up is the shortest follow-up period to achieve some confidence that any protection against COVID-19 is likely to be more than short-lived. The EUA request should include a plan for active follow-up for safety (including deaths, hospitalizations, and other serious or clinically significant adverse events) among individuals administered the vaccine under an EUA in order to inform ongoing benefit-risk determinations to support continuation of the EUA.

2.7 Continuation of Clinical Trials Following Issuance of an EUA for a COVID-19 Vaccine

FDA does not consider availability of a COVID-19 vaccine under EUA, in and of itself, as grounds for immediately stopping blinded follow-up in an ongoing clinical trial or grounds for offering vaccine to all placebo recipients. To minimize the risk that use of an unapproved vaccine under EUA will interfere with long-term assessment of safety and efficacy in ongoing trials, it is critical to continue to gather data about the vaccine even after it is made available under EUA. An EUA request should therefore include strategies that will be implemented to ensure that ongoing clinical trials of the vaccine are able to assess long-term safety and efficacy (including evaluating for vaccine-associated enhanced respiratory disease and decreased effectiveness as immunity wanes over time) in sufficient numbers of participants to support vaccine licensure. These strategies should address how ongoing trial(s) will handle loss of follow-up information for study participants who choose to withdraw from the study in order to receive the vaccine under an EUA.

FDA is aware that some COVID-19 vaccine developers may wish to immediately unblind their trials upon issuance of an EUA in order to rapidly provide vaccine to trial participants who received placebo. Regardless of when vaccination of placebo recipient would occur, there may be advantages to maintaining blinding in a crossover design that provides vaccine to previous placebo recipients and placebo to previous vaccine recipients. Such strategies would impact collection of longer-term placebo-controlled safety data and evaluation of the duration of vaccine efficacy. Ethical and scientific issues associated with offering vaccination to placebo recipients have been discussed in recent statements and articles.[9-11]

2.8 Previous Meetings of the VRBPAC to Discuss Vaccines to Prevent COVID-19

On October 22, 2020, the VRBPAC met in open session to discuss, in general, the development, authorization, and/or licensure of vaccines to prevent COVID-19. No specific application was discussed at this meeting. Topics discussed at the meeting included:

- FDA's approach to safety and effectiveness, and chemistry, manufacturing and control (CMC) data as outlined in the respective guidance documents
- Considerations for continuation of blinded Phase 3 clinical trials if an EUA has been issued for an investigational COVID-19 vaccine

- Studies following licensure and/or issuance of an EUA for COVID-19 vaccines to:
  - Further evaluate safety, effectiveness and immune markers of protection
  - Evaluate the safety and effectiveness in specific populations.

On December 10, 2020, the VRBPAC met in open session to discuss the EUA request of the Pfizer-BioNTech COVID-19 Vaccine for the prevention of COVID-19 in individuals 16 years of age older. Topics discussed at the meeting but not voted upon included Pfizer's plan for continuation of blinded, placebo-controlled follow-up in ongoing trials in the event that the vaccine is made available under EUA and gaps in plans for further evaluation of vaccine safety and effectiveness in populations that receive the Pfizer-BioNTech Vaccine under an EUA. The committee voted in favor of a determination that, based on the totality of scientific evidence available, the benefits of the proposed vaccine outweigh its risks for use in individuals 16 years of age and older.

3. Topics for VRBPAC Discussion

The Vaccines and Related Biological Products Advisory Committee will convene on December 17, 2020, to discuss and provide recommendations on whether based on the totality of scientific evidence available, the benefits of the Moderna COVID-19 Vaccine outweigh its risks for use in individuals 18 years of age and older. The Committee will also discuss what additional studies should be conducted by the vaccine manufacturer following issuance of the EUA to gather further data on the safety and effectiveness of this vaccine.

4. Moderna COVID-19 Vaccine (mRNA-1273)

4.1 Vaccine Composition, Dosing Regimen

The Moderna COVID-19 Vaccine is a white to off-white, sterile, preservative-free frozen suspension for intramuscular injection. The vaccine contains a synthetic messenger ribonucleic acid (mRNA) encoding the pre-fusion stabilized spike glycoprotein (S) of SARS-CoV-2 virus. The vaccine also contains the following ingredients: lipids (SM-102, 1,2-dimyristoyl-rac-glycero-3-methoxypolyethylene glycol-2000 [PEG2000-DMG], cholesterol, and 1,2-distearoyl-sn-glycero-3-phosphocholine [DSPC]), tromethamine, tromethamine hydrochloride, acetic acid, sodium acetate, and sucrose.

The Moderna COVID-19 Vaccine is provided as a frozen suspension [stored between -25° to -15°C (-13° to 5°F)] multi-dose vial containing 10 doses. The vaccine must be thawed prior to administration. After thawing, a maximum of 10 doses (0.5 mL each) can be withdrawn from each vial. Vials can be stored refrigerated between 2° to 8°C (36° to 46°F) for up to 30 days prior to first use. Unopened vials may be stored between 8° to 25°C (46° to 77°F) for up to 12 hours. After the first dose has been withdrawn, the vial should be held between 2° to 25°C (36° to 77°F) and discarded after 6 hours.

The Moderna COVID-19 Vaccine, mRNA-1273 (100 µg) is administered intramuscularly as a series of two doses (0.5 mL each), given 28 days apart.

FDA has reviewed the CMC data submitted to date for this vaccine and has determined that the CMC information is consistent with the recommendations set forth in FDA's Guidance on Emergency Use Authorization for Vaccines to Prevent COVID-19. FDA has determined that the Sponsor has provided adequate information to ensure the vaccine's quality and consistency for authorization of the product under an EUA.

4.2 Proposed Use Under EUA

The proposed use of the vaccine under an EUA is for the prevention of COVID-19 in adults 18 years of age and older.

5. FDA Review of Clinical Safety and Effectiveness Data

5.1 Overview of Clinical Studies

Table 1

53

Table 1. Clinical Trials Submitted in Support of Efficacy and Safety Determinations of the Moderna COVID-19 Vaccine mRNA-1273

Study Number	Type of Study (Efficacy, Safety, Nonclinical)	Participants randomized (N)	Study Design & Type of Control	Test Product(s); Dosing Regimens	Study Status
P301	Efficacy, Safety	30418	A Phase 3, randomized, stratified, observer-blind, placebo-controlled study	mRNA-1273 100 µg	Ongoing-vaccine efficacy demonstrated at the 1st interim analysis
P201	Safety, Immunogenicity	600	A Phase 2a, randomized, observer-blind, placebo-controlled, dose-confirmation study	mRNA-1273 50ug,100µg	Ongoing-Day 57 primary analysis have completed
20-0003*	Safety, Immunogenicity	120	A Phase 1 Open-label dose-ranging study	mRNA-1273 25ug 50ug,100ug 250ug	Ongoing-Day 119 (25ug, 100ug, 250ug), Day 57 (50ug)

5.2 Study mRNA-1273-P301

5.2.1 Design

Study mRNA-1273-P301 is an ongoing randomized, stratified, observer-blind, placebo-controlled study to evaluate the efficacy, safety and immunogenicity of mRNA-1273 administered in 2 doses 28 days apart in adults 18 years of age and older. The study took place in 99 sites in the United States. Participants (N=30,351) were randomized 1:1 to receive intramuscular injections of either 100 µg of mRNA-1273 vaccine (n=15,181) or placebo

(n=15,170) on Day 1 and Day 29. Participants were stratified by age and health risk into one of three groups: 18 to <65 years of age and not at risk for progression to severe COVID-19, 18 to <65 years of age and at risk for progression to severe COVID-19, and ≥65 years of age, with the latter two groups consisting of 41.4% of the study population. Participants were considered at risk for progression to severe COVID-19 if they had underlying comorbidities including diabetes, chronic lung disease, severe obesity, significant cardiovascular disease, liver disease, or infection with HIV. The study included 24,907 (82.1%) participants considered at occupational risk for acquiring SARS-CoV-2 infection, of whom 7,613 (25.1%) were healthcare workers. Other essential workers were also represented. The primary efficacy endpoint was efficacy of the vaccine to prevent protocol-defined COVID-19 occurring at least 14 days after the second dose in participants with negative SARS-CoV-2 status at baseline (i.e., negative RT-PCR and negative serology against SARS-CoV-2 nucleocapsid on Day 1).

Symptoms of COVID-19 experienced by participants during post-vaccination follow-up prompted an unscheduled illness visit and nasopharyngeal (NP) swab. NP samples were tested for SARS CoV-2 at a central laboratory using a reverse transcription-polymerase chain reaction (RT-PCR) test (Viracor; FDA authorized under EUA), or other sufficiently validated nucleic acid amplification-based test (NAAT). The central laboratory NAAT result is used for the case definition, unless it is not possible to test the sample at the central laboratory.

The case-driven study design required 151 COVID-19 cases to trigger the final scheduled efficacy analysis. Two interim analysis timepoints were pre-specified; the first upon accrual of 53 cases and the second upon accrual of 106 cases. The expected duration of study participation is approximately 25 months.

Primary Efficacy Endpoint

The primary efficacy endpoint was efficacy of the vaccine to prevent protocol-defined COVID-19 occurring at least 14 days after the second dose in participants with negative SARS-CoV-2 status at baseline (i.e., negative RT-PCR and negative serology against SARS-CoV-2 nucleocapsid on Day 1). The primary analysis was based on the Per-Protocol Set, defined as all randomized, baseline SARS-CoV-2 negative participants who received planned doses per schedule and have no major protocol deviations. For the primary efficacy endpoint, the case definition for a confirmed COVID-19 case was defined as:

- At least TWO of the following systemic symptoms: Fever (≥38°C), chills, myalgia, headache, sore throat, new olfactory and taste disorder(s), or
- At least ONE of the following respiratory signs/ symptoms: cough, shortness of breath or difficulty breathing, OR clinical or radiographical evidence of pneumonia; and
- NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) positive for SARS-CoV-2 by RT-PCR.

Vaccine efficacy was defined as the percent reduction (mRNA-1273 vs. placebo) in the hazard of the primary endpoint, i.e. VE =1 – Hazard Ratio (HR). A stratified Cox proportional hazard (PH) model using Efron's method to handle ties and with treatment group as the independent variable was used to estimate the HR, where the same stratification factor used for randomization was applied. The primary objective would be met if the null hypothesis of H0: VE ≤30% is rejected at any of the interim or primary analyses at the respective significance level.

The final scheduled efficacy analysis of the primary endpoint was planned when a total of 151 adjudicated cases occurring at least 14 days after the second injection had been accrued. In addition, two interim analyses were planned when 35% (53 cases) and 70% (106 cases) of the

total target number of cases had been accrued. The Lan-DeMets spending function was used for approximating O'Brien-Fleming efficacy bounds to preserve the overall Type I error rate at a one-sided α =0.025, yielding nominal one-sided α of 0.0002, 0.0073, and 0.0227 at the first and second interim and the primary analyses, respectively. As conducted, the first and only interim analysis in the study occurred at 95 adjudicated cases of the primary endpoint, where the null hypothesis of H0: VE ≤30% was evaluated at a one-sided alpha of 0.0047.

Secondary Efficacy Endpoints

Secondary endpoints based on the Per-Protocol Set included the VE of mRNA-1273 to prevent the following:

- Severe COVID-19 (as defined below)
- COVID-19 based on a less restrictive definition of disease (defined below) occurring at least 14 days after the second dose of vaccine
- Death due to COVID-19
- COVID-19 occurring at least 14 days after the first dose of vaccine (including cases that occurred after the second dose)

One additional secondary endpoint was based on the Full Analysis Set (FAS): VE of mRNA-1273 to prevent COVID-19 occurring at least 14 days after the second dose, regardless of prior SARS-CoV-2 infection.

One of the secondary efficacy endpoints assessed COVID-19 as defined by a less restrictive definition: a positive NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) for SARS-CoV-2 by RT-PCR **and** one of the following systemic symptoms:

- fever (temperature ≥38°C), or
- chills,
- cough,
- shortness of breath or difficulty breathing,
- fatigue,
- muscle aches or body aches,
- headache,
- new loss of taste or smell,
- sore throat,
- nasal congestion or rhinorrhea,
- nausea or vomiting, or diarrhea

Another secondary endpoint assessed cases of severe COVID-19, defined as a case of confirmed COVID-19 plus at least one of the following:

- Clinical signs at rest indicative of severe systemic illness (RR ≥30 breaths per minute, HR ≥125 beats per minute, SpO2≤93% on room air at sea level, or PaO2/FiO2<300 mm Hg);
- Respiratory failure or Acute Respiratory Distress Syndrome, (defined as needing high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO);
- Evidence of shock (SBP <90 mm Hg, DBP <60 mm Hg, or requiring vasopressors)
- Significant acute renal, hepatic, or neurologic dysfunction;
- Admission to an ICU;
- Death

Vaccine efficacy of secondary endpoints was estimated from the Cox proportional-hazards model when the primary endpoint reached statistical significance. Estimates based on the Per-Protocol Set were presented with nominal two-sided 95% confidence intervals.

Analysis Populations

For the purposes of analysis, the following populations are defined:

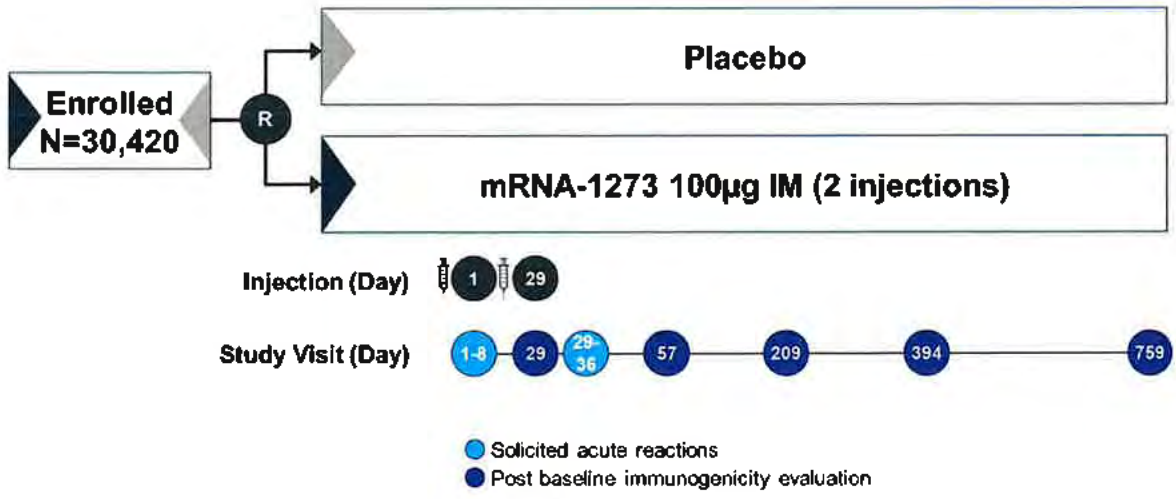
Table 2. Efficacy Set Definitions

Population	Description
Randomized	All participants who are randomized, regardless of the participants' treatment status in the study.
Full Analysis Set	All randomized participants who received at least one dose of Investigational Product (IP).
mITT Set	All participants in the FAS who had no immunologic or virologic evidence of prior COVID-19 (i.e., negative NP swab test at Day 1 and/or bAb against SARS-CoV-2 nucleocapsid below limit of detection [LOD] or lower limit of quantification [LLOQ]) at Day 1 before the first dose of IP.
Per Protocol Set	All participants in the mITT Set who received planned doses of IP per schedule and have no major protocol deviations, as determined and documented by Sponsor prior to DBL and unblinding, that impact critical or key study data.
Safety Set	All randomized participants who received at least one dose of IP.
Solicited Safety Set	All randomized participants who received at least one dose of IP and contributed any solicited adverse reaction data.

Evaluation of Safety

The primary safety objective for all phases was to describe the safety of mRNA-1273 after 1 or 2 doses. In all studies, participants recorded local reactions, systemic events, and antipyretic/pain medication usage from Day 1 through Day 7 after each dose. Unsolicited adverse events (AEs) are collected from dose 1 to 28 after the last dose and medically attended adverse events (MAAEs) and serious AEs (SAEs) from dose 1 to the end of the study. Figure 1 below shows the study safety monitoring plan.

Figure 1. Safety Monitoring Plan, Study 301



Safety assessments included the following:

- Solicited local and systemic adverse reactions (AR) that occurred during the 7 days following each dose (i.e., the day of vaccination and 6 subsequent days). Solicited ARs were recorded daily using eDiaries.
- Unsolicited AEs observed or reported during the 28 days following each dose (i.e., the day of vaccination and 27 subsequent days). Unsolicited AEs are those not included in the protocol-defined solicited AR.
- AEs leading to discontinuation from vaccination and/or study participation from Day 1 through Day 759 or withdrawal from the study.
- Medically Attended Adverse Events (MAAE) from Day 1 through Day 759 or withdrawal from the study.
- Serious Adverse Events (SAEs) from Day 1 through Day 759 or withdrawal from the study.
- Abnormal vital sign measurements.
- Physical examination findings.
- Pregnancy and accompanying outcomes.

Safety laboratory evaluations were not assessed in Study P301 but were collected in the phase 2 Study P201. See Appendix A on page 53.

Potential COVID-19 illnesses and their sequelae were not to be reported as AEs, with the exception of illnesses that met regulatory criteria for seriousness and were not confirmed to be COVID-19. Such illnesses were evaluated and reported as SAEs.

Monitoring for risk of vaccine-enhanced disease was performed by an unblinded team supporting the Data Monitoring Committee that reviewed cases of severe COVID-19 as they were received and reviewed AEs at least weekly for additional potential cases of severe COVID-19. The stopping rule was triggered when the 1-sided probability of observing the same or a more extreme case split was 5% or less when the true incidence of severe disease was the same for vaccine and placebo participants.

The table below shows the Phase 3 safety analyses populations that were used to determine the proportions of study participants who experienced adverse events, including solicited adverse reactions after each dose, unsolicited adverse events, medically attended adverse events, and serious adverse events.

Table 3. Safety Set Definitions

Population	Description
Randomized Set	All participants who are randomized, regardless of the participants treatment status in the study.
Safety Set	All randomized participants who received at least one dose of investigational product. The safety set was used for all analyses of safety except solicited adverse reactions. Participants were included in the treatment group corresponding to the investigational product they received.
Solicited Safety Set	All randomized participants who received at least one dose of investigational product and contributed any solicited adverse reaction data. The solicited safety set was used for the analyses of solicited adverse reactions. Participants were included in the treatment group corresponding to the investigational product they received.
Solicited Safety Set-1st Injection	All randomized participants who received the 1st dose and provided any solicited reaction data.

Population	Description
Solicited Safety Set-2nd Injection	All randomized participants who received the 2nd dose and provided any solicited reaction data.

5.2.2 FDA Assessment of Phase 3 Follow-Up Duration

As of the interim analysis cutoff (November 7, 2020, for efficacy, November 11, 2020, for safety), the proportion of participants across groups who received one dose of vaccine or placebo was 100%, and the proportion of participants who received two doses was 91.9% (92.1% vaccine, 91.7% placebo). The median follow-up after dose 2 was 7 weeks across groups. (For participants who did not receive a second dose of vaccine or placebo, follow-up after dose 2 was zero. Among participants who received dose 2, the median follow-up after the second dose was 50.0 days.) The proportion of participants with at least 1 month of follow-up after dose 2 was 76.7% (77.2% vaccine, 76.2% placebo) and with at least 2 months follow-up after dose 2 was 25.3% (25.7% vaccine, 24.9% placebo). FDA has completed its independent validation and evaluation of the datasets from which the Sponsor's interim safety and efficacy analyses were derived.

A second safety data cutoff was performed on November 25, 2020, and final efficacy analysis performed with a data cutoff of November 21, 2020, when 196 primary endpoint cases accrued. These data include a median follow-up of 2 months (9 weeks) for both efficacy and safety. The proportion of participants with at least 1 month of follow-up after dose 2 was 87.9% (88.2% vaccine, 87.7% placebo) and with at least 2 months follow-up after dose 2 was 53.6% (53.8% vaccine, 53.5% placebo). The Sponsor submitted analyses from the final efficacy analysis (Tables, Figures and Listings) on December 4, 2020, and safety analyses (Tables, Figures and Listings) on December 7, 2020, for FDA review under the EUA. Datasets were also submitted on December 7, 2020 and validated by FDA by December 8, 2020. The review of the second dataset submission for the final scheduled efficacy analysis and safety data through November 25, 2020, was not as comprehensive as that of the interim efficacy data and safety data first submitted in support of the EUA. However, preliminary assessments of safety and efficacy data and analyses from second data cutoff do not demonstrate any notable differences compared with the efficacy and safety analyses from November 7, 2020, and November 11, 2020, respectively, and key safety and efficacy data (e.g., the primary analysis, cases of severe COVID-19, and serious adverse events) from the December 7, 2020, submission were verified. FDA therefore considers the totality of submitted data to satisfy the expectation of a median of 2 months follow-up after completion of the full vaccination regimen.

5.2.3 Participant Disposition and Inclusion in Analysis Populations

Disposition tables are presented below in Table 4 (Per-Protocol Set) and Table 5 (Safety Set). The proportion of participants excluded from the Per-Protocol Set was balanced between treatment groups, with the majority of those excluded due to positive or unknown baseline SARS-CoV-2 status. Overall, few participants were discontinued or lost to follow-up, and these and other analysis population exclusions were generally balanced between treatment groups. In the per protocol population, 26.3% of vaccine recipients and 25.7% of placebo recipients completed at least 2 months follow-up after dose 2.

Table 4. Efficacy Analysis Population Study Disposition[a], mRNA-1273-P301

Disposition	Vaccine Group (N=15208) n (%)	Placebo Group (N=15210) n (%)	Total (N=30418) n (%)

[a] EUA request (interim analysis): November 11, 2020 cutoff
*Percentage based on number of participants in the Safety Set
**Percentage based on number of participants in the Per-Protocol Set

Based on the November 11, 2020 safety data cutoff, an overview of participant disposition is presented in the table below. The proportion of randomized participants who discontinued from the study was 0.9% (288 participants) across study groups, with a greater number in the placebo group (168) compared with the vaccine group (120). The most frequently reported reason was withdrawal of consent (67 participants in the vaccine group, 120 in the placebo group). In addition, 51 participants were lost to follow-up (20 in the vaccine group, 31 in the placebo group). In the vaccine group, 3 participants withdrew due to an adverse event (<0.1%, including 1 participant who withdrew due to a SAE) and 3 participants died during the study. In the placebo group, no participants withdrew due to an adverse event, and 4 participants died during the study.

5.2.4 Demographics and Other Baseline Characteristics

The Per-Protocol Set included 47.4% females and 25.3% of individuals ≥65 years of age. There were 36.5% of participants considered as representing communities of color with 9.7% African American, 4.7% Asian, and <3% from other racial groups; 20% of participants were Hispanic/Latino. A majority of the participants (82%) were considered at occupational risk for SARS-CoV-2 exposure, with 25.4% of participants being healthcare workers. At least one protocol-defined high-risk condition for severe COVID-19 was present in 22.3% of participants, and 4% of participants had two or more high risk conditions. The protocol-specified risk factors were those conditions that placed an individual at increased risk for severe complications of COVID-19 and were selected based on CDC recommendations[12] from March 2020. These conditions included the following:

- Chronic lung disease (e.g., emphysema and chronic bronchitis), idiopathic pulmonary fibrosis and cystic fibrosis) or moderate to severe asthma
- Significant cardiac disease (e.g., heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension)
- Severe obesity (body mass index ≥40 kg/m2)
- Diabetes (Type 1, Type 2 or gestational)
- Liver disease
- HIV infection

There was a similar distribution of demographic characteristics between the treatment groups as well as between the all randomized population, Full Analysis Set, and the Per-Protocol Set.

Table 6. Demographic Characteristics[a], Per-Protocol Set

Characteristic	Vaccine Group (N=13934) n (%)	Placebo Group (N=13883) n (%)	Total (N=27817) n (%)

Age and Health Risk for Severe COVID-19***			
18 to <65 years and not at risk	8309 (59.6)	8323 (60.0)	16632 (59.8)
18 to <65 years and at risk	2098 (15.1)	2061 (14.8)	4159 (15.0)
≥65 years	3527 (25.3)	3499 (25.2)	7026 (25.3)

Source: Sponsor's Table14.1.3.4.2. [a] EUA request (interim analysis): November 11, 2020 data cutoff.
Occupational risk includes: Healthcare Workers, Emergency Response, Retail/Restaurant Operations, Manufacturing and Production Operations, Warehouse Shipping and Fulfillment centers, Transportation and Delivery Services, Border Protection and Military Personnel, and Personal care and in-home services, Hospitality and Tourism Workers, Pastoral, Social or Public Health Workers, Educators and Students.
* High risk is defined as patients who meet at least one of the following criteria (protocol-defined): Chronic lung disease (eg, emphysema and chronic bronchitis, idiopathic pulmonary fibrosis, and cystic fibrosis) or moderate to severe asthma; Significant cardiac disease (eg, heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension); Severe obesity (body mass index ≥40 kg/m2); Diabetes (Type 1, Type 2 or gestational); Liver disease; Human Immunodeficiency Virus (HIV) infection
** Age and health risk for severe COVID-19 is used as stratification factor for randomization.

The demographic characteristics among vaccine and placebo participants in the safety population were similar. There were no significant imbalances in demographic and other baseline characteristics between the per-protocol population and the safety population, with median 7-week follow-up.

Source: Sponsor's Table 14.1.3.2.2 [a] EUA request (interim analysis): November 11 2020 cutoff.
* Occupational risk includes: Healthcare Workers, Emergency Response, Retail/Restaurant Operations, Manufacturing and Production Operations, Warehouse Shipping and Fulfillment centers, Transportation and Delivery Services, Border Protection and Military Personnel, and Personal care and in-home services, Hospitality and Tourism Workers, Pastoral, Social or Public Health Workers, Educators and Students.**
**High risk is defined as patients who meet at least one of the following criteria (protocol-defined): Chronic lung disease (eg, emphysema and chronic bronchitis, idiopathic pulmonary fibrosis, and cystic fibrosis) or moderate to severe asthma; Significant cardiac disease (eg, heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension); Severe obesity (body mass index ≥40 kg/m2); Diabetes (Type 1, Type 2 or gestational); Liver disease; Human immunodeficiency virus (HIV) infection

The following table provides the proportions of participants randomized to each of the protocol-specified strata based on presence or absence of protocol-defined risk factors for severe COVID-19 disease, including age ⩾65 years. The presence of these risk factors was assessed at screening via review of the participants medical history. The protocol specified that at least 25% (and up to 50%) of enrolled participants were to be either ⩾65 years of age or 18 through <65 years of age with a protocol-defined risk factor. As of the November 11, 2020 cutoff, ~25% of participants were age ⩾65 years, and 16.7% of participants were age 18 to <65 years with a protocol-defined risk factor. The remainder of participants (58.6%) were age 18 to <65 years without risks. The proportions of participants in each of these three strata randomized to vaccine or placebo are shown in the table below.

Table 8. Protocol-Defined Risk for Severe COVID-19 Disease, Safety Seta

Participants Risk Categories	Vaccine Group (N=15184) n (%)	Placebo Group (N=15165) n (%)	Total (N=30350) n (%)
Without Any Protocol Risk for Severe COVID-19	11824 (77.9)	11783 (77.7)	23608 (77.8)
With Any Protocol Risk for Severe COVID-19	3360 (22.1)	3382 (22.3)	6742 (22.2)
Chronic Lung Disease	707 (4.7)	741 (4.9)	1448 (4.8)
Significant Cardiac Disease	742 (4.9)	741 (4.9)	1483 (4.9)
Severe Obesity	986 (6.5)	978 (6.4)	1964 (6.5)
Diabetes	1427 (9.4)	1431 (9.4)	2858 (9.4)
Liver Disease	100 (0.7)	96 (0.6)	196 (0.6)
HIV Infection	90 (0.6)	86 (0.6)	176 (0.6)

5.2.5 Vaccine Efficacy

Interim Primary Efficacy Analysis

The interim primary efficacy analysis was based on the Per-Protocol Set, which consisted of all participants with negative baseline SARS-CoV-2 status (i.e., negative RT-PCR for SARS-CoV-2 at Day 1 and/or negative serology against SARS-CoV-2 nucleocapsid) and who received 2 doses of investigational product per schedule with no major protocol deviations. The primary efficacy endpoint was vaccine efficacy (VE) in preventing protocol defined COVID-19 occurring at least 14 days after dose 2. Cases were adjudicated by a blinded committee. The primary

efficacy success criterion would be met if the null hypothesis of VE ≤30% was rejected at the O'Brien Fleming boundary at either the interim or primary analysis. The efficacy analysis presented is based on the data at the first pre-specified interim analysis timepoint consisting of 95 adjudicated cases. As shown in Table 9, in participants ≥18 years of age, there were 5 COVID-19 cases in the vaccine group and 90 COVID-19 cases in the placebo group, with a VE of 94.5%, a lower bound of the 95% CI of 86.5%, and a one-sided p-value of <0.0001 for testing H0: VE ≤30%, which met the pre-specified success criterion. In participants ≥65 years of age in the Per-Protocol Set, there were no COVID-19 cases in the vaccine group and 15 COVID-19 cases in the placebo group.

Table 9. Interim Analysis[a] for Primary Efficacy Endpoint, COVID-19 Starting 14 Days After the 2nd Dose, Per-Protocol Set

Primary Endpoint: COVID-19 (per adjudication committee assessment)	Vaccine Group N=13934 Cases n (%) (Incidence rate per 1,000 person-years)	Placebo Group N=13883 Cases n (%) (Incidence rate per 1,000 person-years)	Vaccine Efficacy (VE) % (95% CI)*	Met Predefined Success Criterion**
All participants	5 (<0.1) 1.840	90 (0.6) 33.365	94.5% (86.5%, 97.8%)	Yes
18 to <65	5 / 10407 (<0.1) 2.504	75 / 10384 (0.7) 37.788	93.4% (83.7%, 97.3%)	NA
65 and older	0 / 3527	15 / 3499 (0.4) 21.046	100%	NA

Source: Sponsor's Table 14.2.2.1.1.1.1, Table 14.2.2.1.1.6.1.1.
COVID-19: symptomatic COVID-19 requiring positive RT-PCR result and at least 2 systemic symptoms or 1 respiratory symptom. Cases starting 14 days after the 2nd dose. All potential COVID-19 cases starting 14 days after the 2nd dose in the clinical database as of 07-Nov-2020 have been sent to adjudication committee, and have been adjudicated for this analysis (07-Nov-2020 is the data cutoff date for efficacy). One case (in the placebo group) was assessed as a case by the adjudication committee but did not meet case definition based on statistical analysis plan (participant had body aches, nasal congestion, rhinorrhea, which were not protocol defined symptoms).
* VE is calculated as 1-ratio of incidence rates (mRNA-1273/placebo) and 95% CI from the stratified Cox proportional hazard model.
**The one-sided p-value is <0.0001 from the stratified Cox proportional hazard model to test the null hypothesis of VE ≤30%, achieving the pre-specified efficacy boundary: the one-sided nominal alpha of 0.0049 based on 95 cases using the Lan-DeMets O'Brien-Fleming spending function.

There were an additional 18 COVID-19 cases which met the protocol-defined primary efficacy endpoint but were not able to be adjudicated in time for the interim analysis. Of these 18 cases, one was in the vaccine group, and 17 were in the placebo group. Vaccine efficacy for the primary efficacy endpoint including these unadjudicated cases was similar to the results presented above.

Interim Subgroup Analyses of Vaccine Efficacy

Subgroup analyses for the primary efficacy endpoint include VE based on age, sex, race and ethnicity, risk factor, and baseline SARS-CoV-2 status and provide additional information on the applicability of these results across the general population. In general, VE among the subgroups are similar to the VE seen in the overall study population. The small number participants and cases in some subgroups, such as participants ≥75 years of age and participants in certain racial subgroups, limits the interpretability of the individual VE results, but are displayed for completeness.

Table 10. Subgroup Analyses of Vaccine Efficacy[a], COVID-19 14 Days After Dose 2 Per Adjudication Committee Assessments, Per-Protocol Set

Subgroup	Vaccine Group Cases / N (%) Incidence rate per 1,000 person-years	Placebo Group Cases / N (%) Incidence rate per 1,000 person-years	VE % (95% CI)*

* VE is calculated as 1-ratio of incidence rates (mRNA-1273/Placebo) and 95% CI from the stratified Cox proportional hazard model. The VE 95% confidence interval is not presented for subgroups for which the lower bound was not evaluable by the statistical methods used for the analysis.
At risk for severe COVID-19 due to comorbidity, regardless of age. High risk is defined as patients who meet at least one of the following criteria (protocol-defined): Chronic lung disease (eg, emphysema and chronic bronchitis, idiopathic pulmonary fibrosis, and cystic f ibrosis) or moderate to severe asthma; Significant cardiac disease (eg, heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension); Severe obesity (body mass index ≥40 kg/m2); Diabetes (Type 1, Type 2 or gestational); Liver disease; Human Immunodeficiency Virus (HIV) infection
**used as stratification factor for randomization

The demographics of the participants with confirmed COVID-19 cases contributing to the primary efficacy analysis are displayed below in Table 11.

Table 11. Demographic Characteristics[a], Participants With COVID-19 Starting 14 Days After Dose 2, Per Adjudication Committee Assessments, Per-Protocol Set

Characteristic	Vaccine (N[a] =5) N[b] (%)	Placebo (N[a] =90) N[b] (%)	Total (N[a] =95) N[b] (%)

[a] N = number of participants in the specified group, or the total sample. This value is the denominator for the percentage calculations. [a] EUA request (interim analysis): November 07 2020 efficacy data cutoff. [a] EUA request (interim analysis): November 07 2020 cutoff.
[b] n = Number of participants with the specified characteristic.

Only 2.2% of participants had evidence of prior infection at study enrollment, and there was only one COVID-19 case starting 14 days after dose 2 reported from this subgroup, which was in a participant in the placebo group. There is insufficient data to conclude on the efficacy of the vaccine in previously infected individuals.

Table 12. Vaccine Efficacy by Baseline SARS-CoV-2 Status[a]: First COVID-19 From 14 Days After Dose 2 Per Adjudication Committee Assessment, Full Analysis Set

Subgroup	Vaccine Group Cases / N (%) Incidence rate per 1,000 person-years	Placebo Group Cases / N (%) Incidence rate per 1,000 person-years	VE % (95% CI)*
Baseline SARS-CoV-2			
Regardless of baseline SARS-CoV-2 status	6/15180	92/15170	93.5% (85.2, 97.2)
Positive	0/341	1/334 (0.3) 17.038	100%
Negative	6/14312 (<0.1) 2.154	90/14370 (0.6) 32.298	93.4% (84.8%, 97.1%)

* VE is calculated as 1-ratio of incidence rates (mRNA-1273/Placebo) and 95% CI from the stratified Cox proportional hazard model. The VE 95% confidence interval is not presented for subgroups for which the lower bound was not evaluable by the statistical methods used for the analysis.

Additional subgroup analyses of the interim primary efficacy analysis were conducted to evaluate the vaccine efficacy, by risk factor for severe COVID-19. VE point estimates were consistent with the efficacy observed for the overall study population, though interpretation of the results is limited by small numbers of participants and cases.

Table 13. Vaccine Efficacy by Risk Factor: First COVID-19 Occurrence From 14 Days After Dose 2, Per Adjudication Committee Assessment, Per-Protocol Set

* VE is calculated as 1-ratio of incidence rates (mRNA-1273/Placebo) and 95% CI from the stratified Cox proportional hazard model. The VE 95% confidence interval is not presented for subgroups for which the lower bound was not evaluable by the statistical methods used for the analysis.
** Post hoc analysis.

Interim Secondary Efficacy Analyses

Severe COVID-19 Cases

All 11 cases of severe COVID-19 at least 14 days after second dose as assessed by the adjudication committee were in the placebo group. Of these 11 participants, 5 had risk factors for severe COVID-19 and 6 did not. Three severe COVID-19 cases resulted in hospitalization and 8 did not. Nine of these cases met the severe COVID-19 case definition based on low oxygen saturation ≤93% on room air without any other severe disease criteria. One participant had low oxygen saturation as well as systolic blood pressure <90 mmHg. One participant had low oxygen saturation and missing data on whether other criteria were met. The vaccine efficacy of this secondary efficacy endpoint is shown in Table 14.

Table 14. Severe COVID-19 Cases Starting 14 Days After Second Dose Based on Adjudication Committee Assessment, Per-Protocol Set

	Vaccine Group N=13934 Cases n (%)	Placebo Group N=13883 Cases n (%) Incidence rate per 1,000 person-years	Vaccine Efficacy (VE) % (95% CI)*
Severe COVID-19	0	11 (<0.1); 4.072	100%

[a] EUA request (interim analysis): Novemer 07 2020 efficacy data cutoff.
* VE is calculated as 1-ratio of incidence rates (mRNA-1273/Placebo) and 95% CI from the stratified Cox proportional hazard model. The VE 95% confidence interval is not presented when the lower bound was not evaluable by the statistical methods used for the analysis.

One participant in the mRNA-1273 group, a participant >65 years of age who had risk factors for severe COVID-19, was hospitalized due to oxygen saturation of 88% on room air 2 months after receiving the second dose of vaccine. There was a verbal report of a positive SARS-CoV-2 RT-PCR test 3 days prior to hospitalization; however, NP swab collected during hospitalization was negative for SARS-CoV-2. Due to absence of a confirmed RT-PCR result at the time of data snapshot, this case was not referred for adjudication and not captured. The pre-hospitalization RT-PCR result was later reported to be positive from an external CLIA-certified laboratory and may represent a severe COVID-19 case with hospitalization in the vaccine group.

There were 4 additional severe COVID-19 cases which met the protocol-defined severe COVID-19 endpoint but were not able to be adjudicated in time for the interim analysis. All 4 cases were in the placebo group.

Other Secondary Efficacy Endpoints

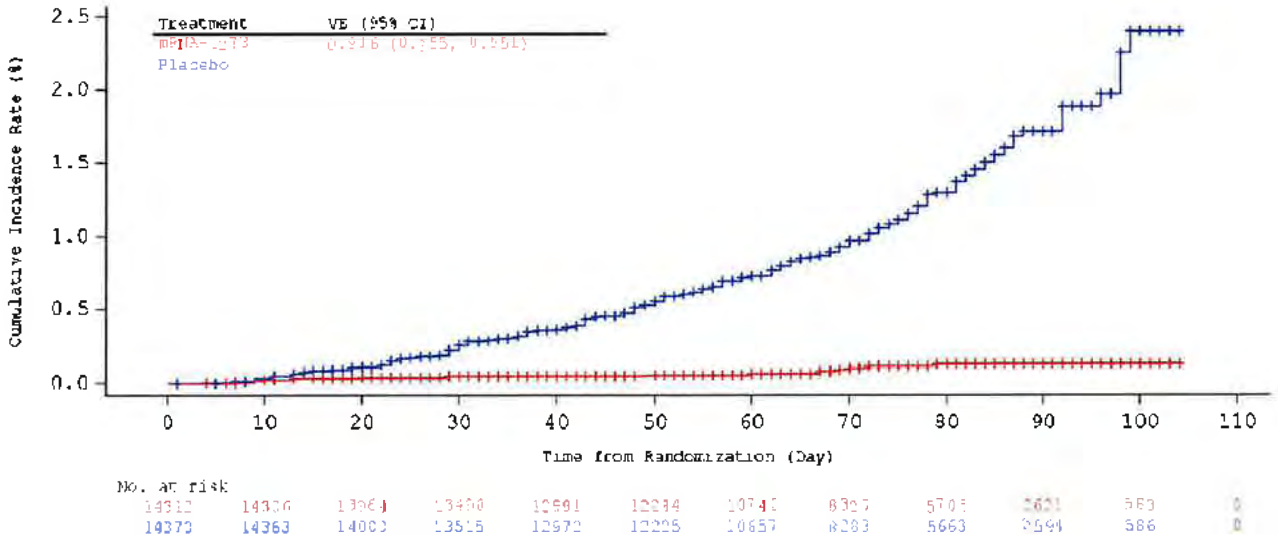
The secondary efficacy endpoint of VE of mRNA-1273 for the prevention of COVID-19 disease based on a less restrictive definition of COVID-19 disease from 14 days after dose 2 showed similar case splits and VE to the primary efficacy endpoints described above. Efficacy against COVID-19 occurring at least 14 days after the first dose of vaccine, including cases that occurred after the second dose, was also similar to the primary endpoint. There were no deaths due to COVID-19 at the time of the interim analysis to enable an assessment of vaccine efficacy against death due to COVID-19.

Cumulative Incidence Curves – Interim Efficacy Analysis

Based on the cumulative incidence curve for cases in the mITT efficacy population after randomization (same as date of dose 1), COVID-19 cases appear to have occurred similarly at low rates for both the mRNA-1273 and placebo groups until around Day 14 after dose 1. The

curves then diverge, with more cases accumulating in the placebo group than the mRNA-1273 group.

Figure 2. Cumulative Incidence Curves for the First COVID-19 Occurrence After Randomization, mITT Set



Additional Interim Efficacy Analyses

Additional analyses were done to assess efficacy against COVID-19 after one dose of mRNA-1273. In participants in the mITT set who only received one dose of the vaccine at the time of the interim analysis, VE after one dose was 80.2% (95% CI 55.2%, 92.5%). These participants had a median follow-up time of 28 days (range: 1 to 108 days). The small, non-random sample and short median follow-up time limits the interpretation of these results. There appears to be some protection against COVID-19 disease following one dose; however, these data do not provide sufficient information about longer term protection beyond 28 days after a single dose.

Table 15. Vaccine Efficacy[a] of mRNA-1273 to Prevent COVID-19 From Dose 1 by Time Period in Participants Who Only Received One Dose, mITT Set

First COVID-19 Occurrence After Dose 1	Vaccine Group N=996 Case n (%)	Placebo Group N=1079 Case n (%)	VE (%) (95% CI)*
After dose 1	7/996 (87.5)	39/1079 (96.7)	80.2% (55.2%, 92.5%)
After dose 1 to 14 days after dose 1	5/996 (38.0)	11/1079 (41.1)	50.8% (-53.6%, 86.6%)
>14 days after dose 1**	2/983 (87.2)	28/1059 (96.2)	92.1% (68.8%, 99.1%)

Surveillance time in person years for given endpoint across all participants within each group at risk for the endpoint
* VE is calculated as 1-ratio of incidence rates (mRNA-1273/Placebo). The 95% CI of VE is calculated using the exact method conditional upon the total number of cases, adjusting for person-years
**Participants who were not at risk (cases or censored at prior time period) are excluded from this analysis
[a] Based on interim analysis: November 7, 2020 efficacy data cutoff.

A similar analysis was conducted to look at vaccine efficacy against severe COVID-19 after one dose. In participants in the mITT group who received only one vaccine, 2 participants in the mRNA-1273 group and 4 participants in the placebo group developed severe COVID-19. Both participants in the vaccine group met the case definition for severe COVID-19 based on oxygen saturation ≤93% on room air. These results should be interpreted cautiously given the small sample size and case number and the short follow-up duration.

Table 16. Vaccine Efficacy[a] of mRNA-1273 to Prevent Severe COVID-19 After Dose 1 in Participants Who Only Received One Dose in mITT Set

	Vaccine Group N=996 Case n (%)	Control Group N=1079 Case n (%)	Vaccine Efficacy (95% CI)
Number of participants with severe COVID-19 starting after dose 1	2 (0.2)	4 (0.4)	42.6% (-300.8, 94.8)

[a] Based on interim analysis : EUA request (interim efficacy analysis): November 7, 2020 efficacy data cutoff.

Final Scheduled Efficacy Analysis

Data from the final scheduled efficacy analysis were submitted as an amendment to the EUA request on December 7, 2020. Analyses of efficacy endpoints beyond those presented below have not been independently verified by the FDA. The median efficacy and safety follow-up for participants in the study at of the time of the final scheduled efficacy analysis (November 21, 2020 efficacy data cutoff) was 9 weeks. Vaccine efficacy against COVID-19 starting 14 days after the second dose was 94.1% (95% CI 89.3%, 96.8%) and was consistent with results obtained from the interim analysis. The VE in participants ≥65 years of age appears to be lower than in younger adults 18 to <65 years (86.4% compared to 95.6%) and lower than observed in the interim analysis (100% based on a total of 15 cases).

Table 17. Final Scheduled Efficacy Analysis, Primary Endpoint, COVID-19 Starting 14 Days After the Second Dose per Adjudication Committee Assessments, Per-Protocol Set

Primary Endpoint: COVID-19 (per adjudication committee assessment)	Vaccine Group N=13934 Cases n (%) (Incidence Rate per 1,000 person-years)*	Placebo Group N=13883 Cases n (%) (Incidence Rate per 1,000 person-years)*	Vaccine Efficacy (VE) % (95% CI)**	Met Predefined Success Criterion***
All participants	11 (<0.1) 3.328	185 (1.3) 56.510	94.1% (89.3%, 96.8%)	Yes
18 to <65 years[1]	7/10551 (<0.1) 2.875	156/10521 (1.5) 64.625	95.6%; (90.6%, 97.9%)	NA
65 years and older[2]	4/3583 (0.1); 4.595	29/3552 (0.8); 33.728	86.4%; (61.4%, 95.5%)	NA

Source: Sponsor's Table 14.2.2.1.1.1.1, Table 14.2.2.1.1.6.1.1
COVID-19: symptomatic COVID-19 requiring positive RT-PCR result and at least 2 systemic symptoms or 1 respiratory symptom. Cases starting 14 days after the second dose. All potential COVID-19 cases starting 14 days after the second dose in the clinical database as of 21-Nov-2020 have been sent to adjudication committee, and have been adjudicated for this analysis (21-Nov-2020 is the data cutoff date for efficacy). One case (in the vaccine group) was adjudicated as a COVID-19 case by the committee but did was meet the case definition per statistical analysis plan due to documented symptoms and positive PCR being more than 14 days apart.
21-Nov-2020 have been sent to adjudication committee, and have been adjudicated for this analysis (21-Nov-2020 is the data cutoff date for efficacy).
* Incidence rate is defined as the number of participants with an event divided by the number of participants at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.
**VE and 95% CI from the stratified Cox proportional hazard model
***The one-sided p-value is <0.0001 from the stratified Cox proportional hazard model to test the null hypothesis of VE ≤30%, achieving the pre-specified efficacy boundary.
[1] Percentage based on number of participants in the 18 to <65 years of age group.
[2] Percentage based on number of participants in the ≥65 years of age group.

Severe COVID-19 Cases

In the primary efficacy analysis, there were an additional 19 cases of severe COVID-19 (one of which resulted in death from COVID-19), for a total of 30 severe COVID-19 cases starting 14 days after dose 2, per adjudication committee assessment. All 30 cases were in the placebo group. Nine of the total 30 severe COVID-19 cases resulted in hospitalization. Of the 19 additional severe cases since the interim analysis, 12 cases met the severe case definition due to low oxygen saturation ≤93% with no other criteria met. The remaining participants met the definition based on the following reasons: death (1 participant), ARDS requiring ECMO (1 participant), low oxygen saturation and renal and neurologic dysfunction (1 participant), low oxygen saturation and low blood pressure (2 participants), need for high flow oxygen (1 participant), low blood pressure only (1 participants). The COVID-19 case which resulted in death was in a 54-year-old participant with diabetes. The possible severe COVID-19 case in a mRNA-1273 vaccine recipient described with the interim efficacy analysis (negative SARS-CoV-2 PCR per the study central laboratory but reported positive PCR per a CLIA-certified external lab) is not included in the per-protocol analysis below.

Table 18. Secondary Efficacy Analysis, Severe COVID-19 Starting 14 Days After the Second Dose per Adjudication Committee Assessments, Per-Protocol Set

Severe Cases 14 Days After Dose 2 Based on Adjudication Committee Assessments	Vaccine Group N=13934 Cases n (%) (Incidence rate per 1,000 person-years)	Placebo Group N=13883 Cases n (%) (Incidence rate per 1,000 person-years)	Vaccine Efficacy (VE) % (95% CI)*
All participants	0	30 (0.2) 9.138	100%

* EUA request (primary analysis): November 21, 2020 efficacy data cutoff.

Efficacy Summary

The data from the planned interim efficacy analysis, with a cutoff date of November 7, 2020, and median follow-up for efficacy of 7 weeks post-dose 2, met the prespecified success criteria established in the study protocol. Efficacy of the vaccine to prevent COVID-19 occurring at least 14 days after dose 2 was 94.5%, (95% CI 86.5%; 97.8%) in participants without prior evidence of SARS-CoV-2 infection. VE was >93% in the group of participants with or without prior infection, although interpretation of data in participants with positive SARS-CoV-2 status at baseline is limited by the small sample size and case numbers in this subgroup. Efficacy outcomes across demographic subgroups were consistent with the efficacy seen in the overall study population. All 11 cases of severe COVID-19 occurring 14 days after the second dose

were in the placebo group, although one severe COVID-19 may have occurred in the vaccine group but did not meet criteria for the protocol-specified case definition. Among participants in the mITT set who only received one dose of vaccine or placebo at the time of the interim analysis, efficacy against COVID-19 starting after dose 1 was 80.2% (95% CI: 55.2%, 92.5%). The efficacy observed after dose 1 and before dose 2, from a post-hoc analysis, cannot support a conclusion on the efficacy of a single dose of the vaccine, because the numbers of participants and time of observation are limited. The trial did not have a single-dose arm to make an adequate comparison.

Data from a final efficacy analysis (data cutoff November 21, 2020) was submitted as an amendment after the initial EUA request. The FDA has not independently verified the complete efficacy data from this dataset, beyond those analyses presented above. The final scheduled efficacy analysis on the primary endpoint, demonstrating a VE point estimate of 94.1% (95% CI: 89.3%, 96.8%), appear to align with the data obtained from the interim analysis, except for a lower efficacy observed in participants ≥65 years of age compared to that in younger adults 18 to <65 years of age and compared to the efficacy estimate from the interim analysis.

5.2.6 Safety

The safety analyses presented in this review are largely derived from the November 11, 2020 dataset that was the basis for the November 30, 2020 EUA request. FDA has not independently verified the complete safety dataset and analyses from the cutoff date of November 25, 2020. However, all new deaths, SAEs, unsolicited adverse events of interest, and pregnancies were reviewed using the cutoff date of November 25, 2020. No additional safety concerns were raised based on the additional data reviewed by FDA or analyses presented by the Sponsor. The safety analyses from the November 25, 2020 cutoff date, as presented by the Sponsor, appear to align with results from the interim analysis in terms of overall rates and types of solicited and unsolicited adverse events.

Adverse events were reported in a higher proportion of vaccine recipients than placebo recipients, and this imbalance was driven by reactogenicity (solicited AEs) reported in the 7 days following each dose of vaccine. The proportions of participants with SAEs, death, and withdrawals due to adverse events were balanced across the study groups. Overall, rates of AEs were lower in participants with baseline positive SARS-CoV-2 status compared with those with baseline negative SARS-CoV-2 status. The tables below provide an overview of the rates of AEs by treatment groups and baseline SARS-CoV-2 status.

Table 19. Participants Reporting at Least One Adverse Event, Among All Participants and by Baseline SARS-COV2 Status (Safety Set)[a]

Adverse Event Type	Vaccine Group n/N (%)	Placebo Group n/N (%)

[a] There were no reports of Grade 4 injection site adverse reactions
[a] EUA request (interim analysis)-November 11, 2020
**Related as assessed by investigator

In subgroup analyses of adults ≥65 years of age, rates of solicited reactions (any, Grade 3 or higher) and all other unsolicited adverse events (AEs) (all and related) were comparable to those observed in all participants. Table 20 below summarizes AEs in participants ≥65 years of age, irrespective of baseline serostatus (as less than 1% of ≥65-year-olds were seropositive at baseline).

Table 20. Adverse Events Among Adults ≥65 Years of Age (Safety Set)[a]

Participants Reporting at Least One	Vaccine Group n/N (%)	Placebo Group n/N (%)
Solicited Safety Set		
Solicited adverse reactions after any injection	3497/3766 (92.9)	2010/3750 (53.6)
Solicited local adverse reaction	3337/3766 (88.6)	859/3750 (22.9)

Solicited Adverse Reactions

Solicited local and systemic adverse reactions with onset within 7 days after each dose were assessed across groups and are presented in the tables below stratified by age (18 to 64 years; ≥65 years) for all participants. Solicited adverse reactions (AR) were recorded daily by study participants using eDiaries and included the assessment of local injection site reactions (pain, erythema, swelling, and lymphadenopathy) and systemic reactions (fever, headache, fatigue, myalgia, arthralgia, chills, and nausea/vomiting).

Local Adverse Reactions

Solicited local AR were reported by the majority of vaccine recipients and at higher rates than placebo recipients. Vaccine recipients reported higher rates of local reactions after dose 1 than dose 2. The proportions of participants reporting any local AR were 84.2% and 88.8% after dose 1 and dose 2 in vaccine recipients, compared to 19.8% and 18.8% after dose 1 and dose 2 in placebo recipients, respectively. The proportions reporting at least one grade 3 local AR were 3.5% and 7.0% after dose 1 and dose 2, respectively in vaccine recipients and 0.5% after any dose in placebo recipients. There were no reports of Grade 4 local reactions after any dose across groups. The majority of vaccine recipients (57.6%) reported onset of local AR on Day 1 while at home, and the median duration was 2 days after dose and 3 days after dose 2.

Overall across both age cohorts, the most frequently reported local AR was pain, reported by 83.7% vs 19.8% of vaccine/placebo recipients after the first dose (2.8% vs 0.4% reported as Grade 3) and 88.4% vs 17.0% of vaccine/placebo recipients after dose 2 (4.1% vs 0.3% reported as Grade 3). The median durations for pain were 2 days and 3 days after dose 1 and dose 2, respectively. The highest rates of pain were in participants 18 to <64 years after dose 2, with 90.1% reporting any pain and 4.6% reporting Grade 3 pain.

Axillary lymphadenopathy (vaccination arm) was the second most frequently reported local AR overall. It was reported in 10.2% vs 4.8% of vaccine/placebo recipients after dose 1 and 14.0% vs 3.9% of vaccine/placebo recipients after dose 2 respectively. Grade 3 axillary lymphadenopathy was reported in 0.3% vs 0.2% vaccine/placebo recipients after dose 1 and in 0.5% vs 0.1% of vaccine/placebo recipients after dose 2. The median duration after dose 1 was 1 day and after dose 2 was 2 days. The highest rates of axillary lymphadenopathy were reported by participants 18 to 64 years of age after dose 2, with 16.0% reporting any severity lymphadenopathy and 0.4% reporting Grade 3 lymphadenopathy.

Local reactions that persisted beyond 7 days after any dose were reported by both vaccine recipients and placebo recipients. Local reactions that persisted were reported by 3.7% of vaccine recipients and 1.3% of placebo recipients across both age cohorts. In the younger age cohort, 4.2% of vaccine recipients and 1.4% of placebo recipients reported a local reaction that persisted beyond 7 days, of which 0.6% of vaccine recipients and <0.1% of placebo recipients reported a Grade 3 reaction that persisted. In the older age cohort, 2.3% of vaccine recipients compared to 1.1% of placebo recipients reported a local reaction that persisted, including 0.5% of vaccine recipients, and <0.1% of placebo recipients reporting Grade 3 local reactions. Frequently reported local reactions persisting beyond 7 days in the younger age cohort in vaccine/placebo recipients were pain (1.5%/0.6%) and axillary lymphadenopathy (2.5%/0.7%), and in the older age cohort pain (1.2%/0.6%) and erythema (0.7%/<0.1%).

Systemic Adverse Reactions

Solicited systemic AR were reported for the majority of vaccine recipients and at higher rates than for placebo recipients. Vaccine recipients had higher rates of systemic reactions after the second dose than the first dose. The proportions of vaccine and placebo participants reporting systemic AR were as follows: reporting any grade was 54.9% vs 42.2% after dose 1 and 79.3% vs 36.5% after dose 2, and reporting Grade 3 was 2.9% vs. 2.0% after dose 1 and 15.7% vs. 2.0% after dose 2, respectively. Across groups and doses <0.1% reported a Grade 4 systemic reaction (mainly fever > 104 °F). The majority of vaccine recipients reported onset of systemic AR while at home either on Day 1 (33.7%) or on Day 2 (37.0%), and the median duration after any dose was 2 days.

Overall, the most frequently reported systemic AR was fatigue, reported by 68.5% of vaccine recipients and 36.1% of placebo recipients. After any dose, Grade 3 fatigue was reported by 9.6% of vaccine participants and 1.3% of placebo recipients. Grade 4 fatigue was reported by 1 participant in the vaccine group and none in the placebo group. After dose 1, any/Grade 3 fatigue was reported by 37.2%/1.0% of vaccine recipients and after dose 2 any/Grade 3 fatigue was reported by 65.2%/9.7% of vaccine recipients. The median duration for fatigue in vaccine recipients was 2 days after any dose. The highest rates of fatigue were reported by participants 18 to 64 years after the 2nd dose, with 67.6% reporting any fatigue, 10.6% reporting Grade 3, and 1 participant reporting Grade 4 (after Dose 1).

Rates of other solicited systemic AR were: headache 63.0% vaccine group vs. 36.5% placebo group; myalgia 59.6% vaccine group vs. 20.1% placebo group; arthralgia 44.8% vaccine group vs. 17.2% placebo group; and chills 43.4% vaccine group vs. 9.5% placebo group. The rates of Grade 3 AR were: headache 5.5% vaccine group vs. 2.2% placebo group; myalgia 8.6% vaccine group vs. 0.6% placebo group; arthralgia 5.1% vaccine group vs. 0.5% placebo group; and chills 1.3% vaccine group vs. 0.2% of placebo group. The median duration was 1 day after dose 1 and 1 to 2 days after dose 2. The highest rates of solicited reactions were observed in participants 18 to 64 years after dose 2 and included the following: headache 62.8% (5.0% reported Grade 3), myalgia 61.3% (10.0% Grade 3), arthralgia 45.2% (5.8% Grade 3), and chills 45.8% (1.5% Grade 3). There was one vaccine recipient in the younger age cohort who also reported Grade 4 arthralgia after dose 1.

Fever was reported after any dose by 14.8% of vaccine participant and 0.6% of placebo recipients. Fever was reported after dose 1 in 0.8% of vaccine recipients and 15.6% of vaccine recipients after dose 2. Grade 3 (≥102.1 °F) was reported by <0.1% (11 participants) of vaccine recipients after Dose 1 and 1.3% (186 participants) of vaccine recipients after dose 2. Grade 4 (≥104.0 °F) fever were reported by 4 vaccine recipients after dose 1 and 11 vaccine recipients after dose 2. In participants 18 to 64 years after dose 2, any fever, Grade 3 fever, and Grade 4 fever were reported in 1,806 participants (17.4%), 168 participants (1.6%), and 10 participants (<0.1%), respectively.

Systemic reactions persisting longer than 7 days were reported in both age cohorts of vaccine and placebo recipients after any dose. In the vaccine group, 11.9% of participants reported a solicited reaction that persisted beyond 7 days compared to 9.5% of placebo participants. In the younger age cohort, 9.8% of vaccine recipients and 8.9% of placebo recipients reported a systemic reaction that persisted beyond 7 days; and 2.0% of vaccine recipients and 1.2% of placebo recipients reported Grade 3 or 4 systemic reaction that persisted beyond 7 days. In the older age cohort, 9.4% of vaccine recipients and 8.1% of placebo recipients reported a systemic reaction that persisted; 1.7% of vaccine recipients (63 participants) and 0.8% of placebo

recipients (31 participants) reported a Grade 3 or 4 reaction that persisted. The most frequently reported systemic reactions that persisted beyond 7 days in vaccine recipients/placebo recipients 18 to 64 years were fatigue (5.7%/5.0%), headache (4.8%/4.0%), myalgia (2.7%/2.7%), and arthralgia (2.6%/2.8%); in the older cohort were fatigue (5.8%/4.5%), arthralgia (3.7%/3.8%), myalgia (2.9%/2.7%), and headache (2.8%/2.7%).

Fever persisted beyond 7 days in 7 vaccine recipients and 4 placebo recipients, all of whom were in the younger age cohort. There were 2 vaccine recipients who reported grade 3 fever that persisted, and none in the placebo group.

Unsolicited AEs

Unsolicited AEs from the November 11, 2020 data cutoff include safety data from participants who had at least 1 month of follow-up after dose 2 (76.7% of all participants) those who had at least 2 months of follow-up after dose 2 (25.3% of all participants). The median study duration following dose 2 was 7 weeks across study groups. Table 25 below shows unsolicited AEs reported through the first data cutoff. Treatment emergent adverse events (AEs) were defined as any event that occurred during the study and was not present before exposure (study vaccine or placebo), any event that occurred during the study and was not present before exposure, or any event already present that worsened after exposure. The following unsolicited adverse events were specified in the protocol:

- Unsolicited AEs observed or reported during the 28 days following each vaccine or placebo dose
- AEs leading to discontinuation from vaccination and/or study participation through Day 759 (study completion) or withdrawal from the study
- Serious adverse events and medically attended adverse events through Day 759 (study completion) or withdrawal from study

Determination of severity for all unsolicited AE were made by the investigators based on medical judgement and definitions of severity as mild, moderate, or severe.

The overall proportions of participants who reported an unsolicited adverse event were generally similar, with numerically slightly higher rates of unsolicited AEs in the vaccine group compared to placebo group for some categories of unsolicited nonserious AEs.

Table 25. Summary of Unsolicited AEs Regardless of Relationship to the Investigational Vaccine, Through 28 Days After Any Vaccination, Study 301, Safety Set

Event Type	Nov 11 Dataset[a] mRNA-1273 (N=15184) n (%)	Nov 11 Dataset[a] Placebo (N=15165) n (%)	Nov 25 Dataset[b] mRNA-1273 (N=15185) n (%)	Nov 25 Dataset[b] Placebo (N=15166) n (%)
All unsolicited AEs	3325 (21.9)	2949 (19.4)	3632 (23.9)	3277 (21.6)
Medically-attended	1215 (8.0)	1276 (8.4)	1372 (9.0)	1465 (9.7)
Severe unsolicited AEs	216 (1.4)	190 (1.3)	234 (1.5)	202 (1.3)
Leading to discontinuation from study vaccine	41 (0.3)	71 (0.5)	50 (0.3)	80 (0.5)
Serious	82 (0.5)	86 (0.6)	93 (0.6)	89 (0.6)
Death	2 (<0.1)	3 (<0.1)	2 (<0.1)	3 (<0.1)

Source:
Abbreviation: AE = adverse event.
Note: An AE is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure. Percentages were based on the number of safety participants.
[a] EUA request (interim analysis)-November 11 2020
[b] Primary efficacy analysis-November 25, 2020

Unsolicited Adverse Events

The table below shows rates of unsolicited AEs that occurred within 28 days of any vaccination and at rates of ≥1% in the vaccine group through the November 11, 2020 data cutoff. The proportion of vaccine recipients who reported an unsolicited AE was 21.9% (3325 participants) compared to 19.4% of placebo participants. A higher frequency of unsolicited adverse events was reported in the vaccine group compared to placebo group and was primarily attributed to local and systemic reactogenicity following vaccination.

Table 26. Unsolicited Adverse Events Occurring in ≥1% of Vaccine Group Participants, by MedDRA Primary System Organ Class and Preferred Term (Safety Analysis Set)[a]

System Organ Class Preferred Term	Vaccine N=15184 n (%) Any	Vaccine N=15184 n (%) Severe	Placebo N=15165 n (%) Any	Placebo N=15165 n (%) Severe
Infections and infestations	521 (3.4)	13 (<0.1)	621 (4.1)	25 (0.2)
Vascular disorders	149 (1.0)	28 (0.2)	138 (0.9)	39 (0.3)
Nervous system disorders	624 (4.1)	27 (0.2)	552 (3.6)	21 (0.1)
Headache	435 (2.9)	19 (0.1)	409 (2.7)	13 (<0.1)
Respiratory, thoracic and mediastinal disorders	480 (3.2)	8 (<0.1)	522 (3.4)	9 (<0.1)
Cough	148 (1.0)	1 (<0.1)	143 (0.9)	1 (<0.1)
Oropharyngeal pain	137 (0.9)	1 (<0.1)	184 (1.2)	3 (<0.1)
Gastrointestinal disorders	426 (2.8)	14 (<0.1)	387 (2.6)	16 (0.1)
Diarrhea	178 (1.2)	2 (<0.1)	147 (1.0)	1 (<0.1)
Skin and subcutaneous tissue disorders	213 (1.4)	4 (<0.1)	158 (1.0)	2 (<0.1)
Musculoskeletal and connective tissue disorders	586 (3.9)	24 (0.2)	521 (3.4)	18 (0.1)
Arthralgia	174 (1.1)	10 (<0.1)	152 (1.0)	2 (<0.1)
Myalgia	172 (1.1)	11 (<0.1)	138 (0.9)	0

System Organ Class Preferred Term	Vaccine N=15184 n (%)	Vaccine N=15184 n (%)	Placebo N=15165 n (%)	Placebo N=15165 n (%)
General disorders and administration site	894 (5.9)	43 (0.3)	560 (3.7)	13 (<0.1)
Fatigue	344 (2.3)	12 (<0.1)	307 (2.0)	7 (<0.1)
Injection site pain	147 (1.0)	6 (<0.1)	49 (0.3)	1 (<0.1)
Injury, poisoning and procedural complications	238 (1.6)	16 (0.1)	262 (1.7)	13 (<0.1)

Source: Sponsor's Tables 14.3.1.8.1 and 14.3.1.17.1
n (%)=number (percentage) of participants reporting the adverse event at least once
[a] EUA request (interim analysis): November 11, 2020 data cutoff.

Unsolicited AEs considered related by the investigator to study vaccination were reported by 7.4% of vaccine recipients and 4.0% of placebo recipients. The proportion of participants who reported severe unsolicited AEs was 1.4% following any vaccine dose (275 participants) and 1.3% following any placebo dose (225 participants). The most frequently reported severe AEs that occurred in greater numbers of vaccine than placebo recipients were headache, myalgia, arthralgia, injection site erythema, and injection site pain (Table 26).

Medically attended adverse events (MAAE) from dose 1 through 28 day following any dose were reported for 8.0% of participants in the vaccine group (1,839 events in 1,215 participants) and 8.4% of those in the placebo group (1,837 events in 1,276 participants). The majority of these events were considered not related to study vaccinations and were primarily attributed to local and systemic reactogenicity following vaccinations.

FDA conducted standard MedDRA queries (SMQs) using FDA-developed software to evaluate for constellations of unsolicited adverse events with onset following dose 1 through the November 11, 2020 cutoff. The SMQs were conducted on adverse event Preferred Terms that could represent various conditions, including but not limited to allergic, neurologic, inflammatory, and autoimmune disorders. FDA assessment of additional safety data accrued through the November 25, 2020 cutoff is ongoing, though specific SMQ of adverse events of clinical interest were assessed.

A SMQ evaluating lymphadenopathy-related events (including injection site lymphadenopathy, lymph node pain, and lymphadenitis) through the November 25, 2020 data cut demonstrated a numerical imbalance across study groups, with 1.1% of vaccine recipients (191 events in 173 vaccine recipients) compared to 0.63% of placebo recipients (109 events in 95 participants) reporting such events in the Safety Set. The rates reported in the older cohort (≥65 years) were 0.74% (28 events in 28 participants) in vaccine recipients compared to 0.35% (16 events in 13 participants) in placebo recipients. The rates reported in the younger cohort (18-64 years) were 1.3% (163 events in 145 participants) in vaccine recipients and 0.72% (93 events in 82 participants) in placebo recipients. These events support a plausible relationship to study vaccination and were also reported in the evaluation of solicited local adverse reactions. Local axillary swelling/tenderness was reported in approximately 19% of participants during the 7 days following any dose in the Solicited Safety Set. The median duration following any dose was 1 to 2 days, and <1% reported Grade 3 axillary swelling/tenderness.

A SMQ evaluating hypersensitivity-related adverse events through the November 25, 2020 data cutoff demonstrated a numerical imbalance across study groups, with 1.5% of vaccine recipients (258 events in 233 participants) and 1.1% of placebo recipients (185 events in 166 participants) reporting such events in the Safety Set. In the older cohort (age ≥65 years) which

comprised 24.8% of the Safety Set, the rates of hypersensitivity were 1.8% (74 events in 68 participants) in vaccine recipients and 1% (45 events in 38 participants) in placebo recipients. In the younger age cohort (18-64 years), the rates were 1.5% (184 events in 165 participants) in vaccine recipients compared to 1.1% (140 events in 128 participants). Overall, the most frequently reported AEs in the hypersensitivity SMQ were injection site rash (0.24% vaccine, 0.01% placebo), injection site urticaria (0.1% vaccine, 0% placebo), and rash maculo-papular (0.07% vaccine, 0.01% placebo). There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine.

A query of specific adverse events of clinical interest in the Safety Set through November 25, 2020 demonstrated a small imbalance in the number of participants reporting Bell's palsy (facial paralysis), with 3 vaccine recipients and 1 placebo recipient reporting this MAAE. One case of Bell's palsy in the vaccine group was considered a SAE; a 67-year-old female with diabetes was hospitalized for stroke due to new facial paralysis 32 days after vaccination. This case was reported as resolving. Another Bell's palsy case in the vaccine group occurred 28 days after vaccination in a 30-year-old female who reported an upper respiratory infection 27 days prior to onset of her facial paralysis. This case was reported as resolved. An additional case of Bell's palsy in the vaccine group was reported with the primary analysis safety data (November 25, 2020 data cutoff) and occurred 22 days after vaccination in a 72-year-old female; this event was still ongoing at the time of safety report. The case in the placebo group, reported as resolving, occurred 17 days post injection in a 52-year-old-male. Causality assessment is confounded by predisposing factors in these participants. However, considering the temporal association and biological plausibility, a potential contribution of the vaccine to the manifestations of these events of facial palsy cannot be ruled out. FDA will recommend surveillance for cases of Bell's palsy with deployment of the vaccine into larger populations. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of adverse events, including other neurologic, neuro-inflammatory, and thrombotic events, that would suggest a causal relationship to the Moderna COVID-19 vaccine.

Immediate Adverse Events

Immediate solicited reactions occurring within 30 minutes of vaccination were infrequent and there does not appear to be an imbalance between the treatment groups. Review of unsolicited AEs that occurred within 30 minutes of vaccination demonstrated comparable rates across study groups (0.6% vaccine, 0.6% placebo), and none of the events reported in the vaccine group were considered serious.

Study Withdrawals due to an Adverse Event (Safety Set)

Adverse events that led to discontinuation of vaccination were reported in 0.3% in the vaccine group and 0.5% in the placebo group. Following the November 25, 2020 cutoff, 4 participants were withdrawn from the study due to an adverse event (2 vaccine recipients and 2 placebo recipients). The two AEs reported in the vaccine group were acute pancreatitis and road traffic accident, and the two AEs reported in the placebo group were incarcerated hernia and duodenal ulcer hemorrhage. FDA's review of data through this latter time point is ongoing.

Serious Adverse Events

Deaths

As of December 3, 2020, 13 deaths were reported (6 vaccine, 7 placebo). Two deaths in the vaccine group were in participants >75 years of age with pre-existing cardiac disease; one

participant died of cardiopulmonary arrest 21 days after dose 1, and one participant died of myocardial infarction 45 days after dose 2. Another two vaccine recipients were found deceased at home, and the cause of these deaths is uncertain: a 70-year-old participant with cardiac disease was found deceased 57 days after dose 2, and a 56-year-old participant with hypertension, chronic back pain being treated with opioid medication died 37 days after dose 1 (The official cause of death was listed as head trauma). One case was a 72-year-old vaccine recipient with Crohn's disease and short bowel syndrome who was hospitalized for thrombocytopenia and acute kidney failure due to obstructive nephrolithiasis 40 days after dose 2 and developed complications resulting in multiorgan failure and death. One vaccine recipient died of suicide 21 days after dose 1. The placebo recipients died from myocardial infarction (n=3), intra-abdominal perforation (n=1), systemic inflammatory response syndrome in the setting of known malignancy (n=1), COVID-19 (n=1), and unknown cause (n=1). These deaths represent events and rates that occur in the general population of individuals in these age groups.

Non-fatal Serious Adverse Events

Among participants who received at least one dose of vaccine or placebo (N=30,351), the proportion of participants who reported at least one SAE from dose 1 to the primary analysis cutoff date (November 25, 2020) was 1% in the mRNA-1273 group and 1% in the placebo group. The most common SAEs occurring at higher rates in the vaccine group than the placebo group were myocardial infarction (0.03% in vaccine group, 5 cases vs. 3 cases in placebo group), cholecystitis (0.02% in vaccine group, 3 cases vs. 0 cases in placebo group), and nephrolithiasis (0.02% in vaccine group, 3 cases vs. 0 cases in placebo group). The small numbers of cases of these events do not suggest a causal relationship. The most common SAEs occurring at higher rates in the placebo arm than the vaccine arm, aside from COVID-19 (0.1% in placebo group), were pneumonia (0.05% in placebo group) and pulmonary embolism (0.03% in placebo group). Occurrence of other SAEs, including cardiovascular SAEs, were otherwise balanced between treatment groups.

As of November 25, 2020, 7 SAEs (4.8%) in the mRNA-1273 group and 5 (3.3%) in the placebo group were assessed by the investigator as related to study vaccination (Table 27). Of the 7 SAEs in the mRNA-1273 group, the Sponsor assessed 4 as related and 3 as unrelated to the vaccine.

Table 27. SAEs Considered Related by Investigator

Investigational Product	SAE	Onset (days after last dose)	Demographics/ Risk factors	Resolution	Related per Investigator/ Moderna
mRNA-1273	Intractable nausea and vomiting	1	65 F; history of headaches and severe nausea requiring hospitalization	Resolved	Yes/Yes
mRNA-1273	Facial swelling	1	46 F; dermal filler cosmetic injection 6 months prior	Resolved	Yes/Yes
mRNA-1273	Facial swelling	2	51 F; dermal filler cosmetic injection 2 weeks prior	Resolved	Yes/Yes
mRNA-1273	Rheumatoid arthritis	14	57 M; hypothyroid	Unresolved	Yes/Yes
mRNA-1273	Dyspnea with exertion, peripheral edema	8	66 F; diabetes, hypertension	Resolving	Yes/No

Investigational Product	SAE	Onset (days after last dose)	Demographics/ Risk factors	Resolution	Related per Investigator/ Moderna
mRNA-1273	Autonomic dysfunction	24	46 F; hypothyroid; possible sinus infection	Unresolved	Yes/No
mRNA-1273	B-cell lymphocytic lymphoma	31	75 F; history of metastatic lung cancer, breast cancer	Unresolved	Yes/No
Placebo	Polymyalgia rheumatica	15	83 M; chronic low back pain	Resolving	Yes/Yes
Placebo	Facial swelling, paresthesia, anxiety	7	41 F; dental procedure 2 weeks prior	Resolved	Yes/No
Placebo	Procedural hemorrhage	16	52 M; aortic stenosis, hyperlipidemia; aspirin intake	Resolved	Yes/No
Placebo	Pulmonary embolism	24	59 M; smoking	Unresolved	Yes/No
Placebo	Pneumonia and myocardial infarction	29	70 M; coronary artery disease, chronic kidney disease, diabetes	Resolved	Yes/No

There was one event of lip angioedema 2 days after vaccination in a 29-year-old female participant in the vaccine group which was classified as medically significant but not considered an SAE. The participant has a history of dermal filler injection in the lips (unknown how long prior to vaccination). She reported having a similar reaction after receipt of an influenza vaccine in the past. Taken in context with the SAEs of facial swelling which occurred in 2 participants who had previous history of cosmetic filler injections, it is possible the localized swelling in these cases is due to an inflammatory reaction from interaction between the immune response after vaccination and the dermal filler. This phenomenon has been reported after natural infection (e.g., after an influenza-like illness).

In FDA's opinion following review of the narratives, 3 SAEs are considered likely related, including the one report of intractable nausea/vomiting and 2 reports of facial swelling. The possibility that the vaccine contributed to the SAE reports of rheumatoid arthritis, peripheral edema/dyspnea with exertion, and autonomic dysfunction cannot be excluded. The vaccine was unlikely to have contributed to the other SAEs assessed by the investigator as related. As described in detail in a previous section, there was one report of Bell's palsy in the vaccine arm which occurred 32 days after vaccination; both the investigator and the Sponsor assessed this event as unrelated to the study vaccine, but in FDA's assessment a causal relationship cannot be definitively excluded.

Subgroup Analyses

There were no specific safety concerns identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection, and occurrence of solicited, unsolicited, and serious adverse events in these subgroups were generally consistent with the overall study population.

Pregnancies

Study participants of childbearing potential were screened for pregnancy prior to each vaccination, with a positive test resulting in exclusion or discontinuation from study vaccination. The study is collecting outcomes for all reported pregnancies that occur after vaccination, or

before vaccination and not detected by pre-vaccination screening tests. Thirteen pregnancies were reported through December 2, 2020 (6 vaccine, 7 placebo). Study vaccination occurred prior to the last menstrual period (LMP) in 5 participants (2 vaccine, 3 placebo), within 30 days after LMP in 5 participants (2 vaccine, 3 placebo), >30 days after LMP in 2 participants (1 vaccine, 1 placebo), and date of LMP not known in 1 participant (1 vaccine, 0 placebo). Unsolicited AEs related to pregnancy include a case of spontaneous abortion and a case of elective abortion, both in the placebo group. One participant in the placebo group is lost to follow-up. Pregnancy outcomes are otherwise unknown at this time.

A combined developmental and perinatal/postnatal reproductive toxicity study of mRNA-1273 in rats was submitted to FDA on December 4, 2020. FDA review of this study concluded that mRNA1273 given prior to mating and during gestation periods at dose of 100 µg did not have any adverse effects on female reproduction, fetal/embryonal development, or postnatal developmental except for skeletal variations which are common and typically resolve postnatally without intervention.

Safety Summary

The information provided by the Sponsor was adequate for review and to make conclusions about the safety of the mRNA-1273 vaccine in the context of the proposed indication and population for intended use under EUA. The number of participants in the Phase 3 safety population (N=30,350; 15,184 vaccine,15,165 placebo) meets the expectations described in FDA's Guidance on Development and Licensure of Vaccines to Prevent COVID-19 for efficacy. The initial EUA request was based on data from the pre-specified interim analysis (November 11, 2020 data cutoff) with a median follow-up duration of 7 weeks after dose 2; this interim analysis data is the primary basis of this EUA review and conclusions. Data and analyses from a November 25, 2020 data cut with a median duration of at least 2 months follow-up after completion of the 2-dose primary vaccination series was submitted as an amendment to the EUA request on December 7, 2020. The FDA has not independently verified the complete safety data from the primary analysis, aside from all new deaths (including those reported through December 3, 2020) and SAEs. No new safety concerns have been identified. The rates and types of solicited adverse reactions and unsolicited adverse events are unlikely to change significantly with an additional 2 weeks of follow-up. The totality of the data package submitted in the EUA request meets the Agency's expectations on the minimum duration of follow-up.

Local site reactions and systemic solicited events after vaccination were frequent and mostly mild to moderate. The most common solicited adverse reactions were injection site pain (91.6%), fatigue (68.5%), headache (63.0%), muscle pain (59.6%), joint pain (44.8%), and chills (43.4%); 0.2% to 9.7% were reported as severe, with severe solicited adverse reactions being more frequent after dose 2 than after dose 1 and generally less frequent in adults ≥65 years of age as compared to younger participants. Among adverse events of clinical interest, lymphadenopathy was reported in 173 participants (1.14%) in the vaccine group and 95 participants (0.63%) in the placebo group. There was a numerical imbalance in hypersensitivity adverse events across study groups, with 1.5% of vaccine recipients and 1.1% of placebo recipients reporting such events in the Safety Set. There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine. Throughout the safety follow-up period to date, there has been three reports of Bell's palsy in the vaccine group and one in the placebo group. Currently available information is insufficient to determine a causal relationship with the vaccine. There were no other notable patterns or numerical imbalances between treatment groups for specific categories of adverse events (including other neurologic, neuro-inflammatory, and thrombotic events) that would suggest a causal relationship to mRNA-

1273.

As of December 3, 2020, there were a total of 13 deaths reported in the study (6 vaccine, 7 placebo). These deaths represent events and rates that occur in the general population of individuals in these age groups. The frequency of non-fatal serious adverse events was low and without meaningful imbalances between study arms (1% in the mRNA-1273 group and 1% in the placebo group). The most common SAEs in the vaccine group which were numerically higher than the placebo group were myocardial infarction (0.03%), cholecystitis (0.02%), and nephrolithiasis (0.02%), although the small numbers of cases of these events do not suggest a causal relationship. The most common SAEs in the placebo arm which were numerically higher than the vaccine arm, aside from COVID-19 (0.1%), were pneumonia (0.05%) and pulmonary embolism (0.03%).

6. Sponsor's Plans for Continuing Blinded, Placebo-Controlled Follow-Up

ModernaTX expects that participants, including approximately 25% who are healthcare workers, may request unblinding to receive mRNA-1273 or another vaccine potentially available under EUA external to the trial. More extensive participant-driven crossover would be expected to alter the composition of the trial population, with greatly increased participant dropout due to a large proportion of participants belonging to priority vaccination groups desiring to be vaccinated with vaccine made available under EUA. ModernaTX is evaluating the opportunity to amend the protocol to proactively reconsent participants who received placebo to be offered mRNA-1273 vaccination and to remain in the trial, enabling ModernaTX to continue to collect the relevant safety and effectiveness data over the entire two years of follow-up while increasing the likelihood of retaining participants on trial. Adverse events among those vaccinated within the trial will be captured, regardless of the treatment group to which the participants were originally allocated, over the entire follow-up period of 24 months.

7. Pharmacovigilance Activities

The Sponsor submitted a Pharmacovigilance Plan to monitor safety concerns that could be associated with the Moderna COVID-19 Vaccine. The Sponsor identified vaccine-associated enhanced disease (which includes but is not limited to vaccine-associated enhanced respiratory disease) and anaphylactic reactions (including anaphylaxis) as important potential risks. Use in the pediatric population, use in pregnant and breast-feeding women, immunogenicity in participants with immunosuppression, concomitant administration with non-COVID vaccines, long-term safety and long-term effectiveness are areas the Sponsor identified as missing information.

The Sponsor will conduct both passive and active surveillance activities for continued vaccine safety monitoring. Passive surveillance activities will include submitting spontaneous reports of the following events to the Vaccine Adverse Event Reporting System (VAERS) within 15 days:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in adults
- Cases of COVID-19 that result in hospitalization or death

The Sponsor will also conduct periodic aggregate review of safety data and proposed to submit periodic safety reports at quarterly intervals, or at another interval specified by FDA. FDA has

requested that periodic reports be submitted monthly. Each periodic safety report is required to contain descriptive information which includes:

- A narrative summary and analysis of adverse events submitted during the reporting interval, including interval and cumulative counts by age groups, special populations (e.g., pregnant women), and adverse events of special interest
- Newly identified safety concerns in the interval
- Actions taken since the last report because of adverse experiences (e.g., changes made to Vaccination Provider fact sheets, changes made to studies or studies initiated)

Sponsor studies will include completion of long-term follow-up from ongoing clinical trials as well as the following three planned surveillance studies.

- Pregnancy Cohort: The Sponsor plans to establish a passive pregnancy registry to monitor vaccination during pregnancy within populations expected to receive the vaccine under EUA, and to submit a protocol for FDA review and approval.

- Active Follow-up for Safety: This study is an active safety surveillance activity conducting retrospective analyses of medical and pharmacy claims data to address three objectives; estimation of background rates of 23 prespecified adverse events of special interest (AESI), descriptive analyses of observed versus expected rates, and self-controlled risk interval analyses that will be conducted if certain criteria are met from the descriptive analyses. The planned study duration is through December 2022.

- Real World Effectiveness Study: This study is a prospective cohort study to be conducted at Kaiser Permanente Southern California to evaluate vaccine effectiveness in preventing the following outcomes: laboratory confirmed and clinical COVID-19 infection, hospitalization, and mortality for COVID-19. Vaccinated participants will receive Moderna COVID-19 Vaccine between January 1, 2021 and December 31, 2021, and the comparator group will be age matched, unvaccinated KPSC members. The planned study duration is through December 31, 2023.

FDA will provide feedback on these studies after further review of protocols once submitted by the Sponsor.

Reporting to VAERS and ModernaTX, Inc.

Providers administering the Moderna COVID-19 Vaccine must report to VAERS (as required by the National Childhood Vaccine Injury Act) and to ModernaTX the following information associated with the vaccine of which they become aware:

- Vaccine administration errors whether or not associated with an adverse event
- Serious adverse events (irrespective of attribution to vaccination)
- Cases of Multisystem Inflammatory Syndrome in adults
- Cases of COVID-19 that result in hospitalization or death

Additional VAERS Reporting

An additional source of VAERS reports will be through a program administered by the CDC known as v-safe. V-safe is a smartphone-based opt-in program that uses text messaging and web surveys from CDC to check in with vaccine recipients for health problems following COVID-19 vaccination. The system also will provide telephone follow-up to anyone who reports

medically significant (important) adverse events. Responses indicating missed work, inability to do normal daily activities, or that the recipient received care from a doctor or other healthcare professional will trigger the VAERS Call Center to reach out to the participant and collect information for a VAERS report, if appropriate.

8. Benefit/Risk Assessment in the Context of Proposed Indication and Use Under EUA

8.1 Known Benefits

The known benefits among recipients of the proposed vaccine relative to placebo are:

- Reduction in the risk of confirmed COVID-19 occurring at least 14 days after the second dose of vaccine
- Reduction in the risk of confirmed severe COVID-19 occurring at least 14 days after the second dose of vaccine

The 2-dose vaccination regimen was highly effective in preventing PCR-confirmed COVID-19 occurring at least 14 days after receipt of the second dose. Secondary efficacy analyses showed consistency with outcomes in the primary efficacy analysis; the vaccine was effective in preventing COVID-19 using a less restrictive definition of the disease and considering all cases starting 14 days after the first injection. Efficacy findings in the interim analysis were also consistent across various subgroups, including racial and ethnic minorities, participants ages 65 years and older, and those at risk for severe COVID-19 disease due to obesity, diabetes, cardiac disease, liver disease, chronic lung disease, mild to severe asthma, and infection with HIV, although the efficacy estimate in participants ages 65 years and older was slightly lower in the primary efficacy analysis.

8.2 Unknown Benefits/Data Gaps

Duration of protection

As the interim and final analyses have a limited length of follow-up, it is not possible to assess sustained efficacy over a period longer than 2 months.

Effectiveness in certain populations at high-risk of severe COVID-19

Although the proportion of participants at high risk of severe COVID-19 is adequate for the overall evaluation of safety in the available follow-up period, the subsets of certain groups such as immunocompromised individuals (e.g., those with HIV/AIDS) are too small to evaluate efficacy outcomes.

Effectiveness in individuals previously infected with SARS-CoV-2

Limited data suggest that individuals with prior SARS-CoV-2 infection can be at risk of COVID-19 (i.e., re-infection) and may benefit from vaccination. Regarding the benefit of the mRNA-1273 for individuals with prior infection with SARS-CoV2, participants with a known history of SARS-CoV-2 infection were excluded from the Phase 3 study, and there was only one case of COVID-19 among study participants with positive SARS-COV-2 infection status at baseline. Thus, the study was not designed to assess the benefit in individuals with prior SARS-CoV-2 infection.

Effectiveness in pediatric populations

No efficacy data are available from participants ages 17 years and younger.

Future vaccine effectiveness as influenced by characteristics of the pandemic, changes in the virus, and/or potential effects of co-infections

The study enrollment and follow-up occurred during the period of July 27, 2020 to November 21, 2020, in sites across the United States. The evolution of the pandemic characteristics, such as increased attack rates, increased exposure of subpopulations, as well as potential changes in the virus infectivity, antigenically significant mutations to the S protein, and/or the effect of co-infections may potentially limit the generalizability of the efficacy conclusions over time. Continued evaluation of vaccine effectiveness following issuance of an EUA and/or licensure will be critical to address these uncertainties.

Vaccine effectiveness against asymptomatic infection

Data are limited to assess the effect of the vaccine in preventing asymptomatic infection as measured by detection of the virus and/or detection of antibodies against non-vaccine antigens that would indicate infection rather than an immune response induced by the vaccine. Additional evaluations will be needed to assess the effect of the vaccine in preventing asymptomatic infection, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against long-term effects of COVID-19 disease

COVID-19 disease may have long-term effects on certain organs, and at present it is not possible to assess whether the vaccine will have an impact on specific long-term sequelae of COVID-19 disease in individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 should translate to overall prevention of COVID-19-related sequelae in vaccinated populations, though it is possible that asymptomatic infections may not be prevented as effectively as symptomatic infections and may be associated with sequelae that are either late-onset or undetected at the time of infection (e.g., myocarditis). Additional evaluations will be needed to assess the effect of the vaccine in preventing long-term effects of COVID-19, including data from clinical trials and from the vaccine's use post-authorization.

Vaccine effectiveness against mortality

A larger number of individuals at high risk of COVID-19 and higher attack rates would be needed to confirm efficacy of the vaccine against mortality. However, non-COVID vaccines (e.g., influenza) that are efficacious against disease have also been shown to prevent disease-associated death.[13-16] Benefits in preventing death should be evaluated in large observational studies following authorization.

Vaccine effectiveness against transmission of SARS-CoV-2

Data are limited to assess the effect of the vaccine against transmission of SARS-CoV-2 from individuals who are infected despite vaccination. Demonstrated high efficacy against symptomatic COVID-19 may translate to overall prevention of transmission in populations with high enough vaccine uptake, though it is possible that if efficacy against asymptomatic infection were lower than efficacy against symptomatic infection, asymptomatic cases in combination with reduced mask-wearing and social distancing could result in significant continued transmission. Additional evaluations including data from clinical trials and from vaccine use post-authorization will be needed to assess the effect of the vaccine in preventing virus shedding and transmission, in particular in individuals with asymptomatic infection.

8.3 Known Risks

The vaccine elicited increased local and systemic adverse reactions as compared to those in the placebo arm, usually lasting a few days. The most common solicited adverse reactions were pain at injection site (91.6%), fatigue (68.5%), headache (63.0%), muscle pain (59.6%), joint pain (44.8%), and chills (43.4%). Adverse reactions characterized as reactogenicity were generally mild to moderate; 0.2% to 9.7% of these events were reported as severe, with severe solicited adverse reactions being more frequent after dose 2 than after dose 1 and generally less frequent in older adults (≥65 years of age) as compared to younger participants. Among reported unsolicited adverse events, lymphadenopathy occurred much more frequently in the vaccine group than the placebo group and is plausibly related to vaccination. The number of participants reporting hypersensitivity-related adverse events was numerically higher in the vaccine group compared with the placebo group (258 events in 233 participants [1.5%] vs. 185 events in 166 participants [1.1%]). There were no anaphylactic or severe hypersensitivity reactions with close temporal relation to the vaccine.

Serious adverse events, while uncommon (1.0% in both treatment groups), represented medical events that occur in the general population at similar frequency as observed in the study. Of the 7 SAEs in the mRNA-1273 group that were considered as related by the investigator, FDA considered 3 as related: intractable nausea and vomiting (n=1), facial swelling (n=2). For the serious adverse events of rheumatoid arthritis, peripheral edema/dyspnea with exertion, and autonomic dysfunction, a possibility of vaccine contribution cannot be excluded. For the event of B-cell lymphoma, an alternative etiology is more likely. An SAE of Bell's palsy occurred in a vaccine recipient, for which a causal relationship to vaccination cannot be concluded at this time.

No specific safety concerns were identified in subgroup analyses by age, race, ethnicity, medical comorbidities, or prior SARS-CoV-2 infection.

8.4 Unknown Risks/Data Gaps

Safety in certain subpopulations

There are currently insufficient data to make conclusions about the safety of the vaccine in subpopulations such as children less than 18 years of age, pregnant and lactating individuals, and immunocompromised individuals.

FDA review of a combined developmental and perinatal/postnatal reproductive toxicity study of mRNA-1273 in female rats concluded that mRNA1273 given prior to mating and during gestation periods at dose of 100 µg did not have any effects on female reproduction, fetal/embryonal development, or postnatal developmental except for skeletal variations which are common and typically resolve postnatally without intervention

Adverse reactions that are very uncommon or that require longer follow-up to be detected

Following authorization of the vaccine, use in large numbers of individuals may reveal additional, potentially less frequent and/or more serious adverse events not detected in the trial safety population of approximately 30,000 participants over the period of follow-up at this time. Active and passive safety surveillance will continue during the post-authorization period to detect new safety signals.

Although the safety database revealed an imbalance of cases of Bell's palsy (3 in the vaccine group and 1 in the placebo group), causal relationship is less certain because the number of cases was small and not more frequent than expected in the general population. Further signal detection efforts for these adverse events will be informative with more widespread use of the vaccine.

Vaccine-enhanced disease

Available data do not indicate a risk of vaccine-enhanced disease, and conversely suggest effectiveness against severe disease within the available follow-up period. However, risk of vaccine-enhanced disease over time, potentially associated with waning immunity, remains unknown and needs to be evaluated further in ongoing clinical trials and in observational studies that could be conducted following authorization and/or licensure.

10. Appendix A. Phase 1 and 2 Studies

Study DMID Protocol 20-0003

Study Design
DMID Protocol 20-0003 is an ongoing Phase 1, open-label, first-in-human, dose-ranging study to evaluate the safety and immunogenicity of mRNA-1273 in healthy adults 18 years of age and older. A total of 120 participants without risk factors for progression to severe COVID-19 were enrolled into one of 10 age and dose cohorts to receive 2 injections of 25 µg, 50 µg, 100 µg, or 250 µg of mRNA-1273 given 28 days apart. The study included 60 participants 18 through 55 years of age, 30 participants 56 through 70 years of age, and 30 participants 71 years and older. Participants will be followed safety and immunogenicity for 12 months after last vaccination.

Study Objectives/Endpoints Relevant to the EUA
The immunogenicity objectives are to evaluate the binding antibody (bAb) concentrations for spike IgG as measured by ELISA and neutralizing antibody (nAb) titers as measured by PsVNA for all dose levels at baseline and at various time points after vaccination. The study also evaluated T-cell responses elicited by the mRNA-1273 vaccine as assessed by an intracellular cytokine stimulation assay. All participants are followed for solicited adverse reactions through 7 days post each vaccination. Unsolicited AEs are collected through 28 days after each vaccination. All SAEs and medically attended adverse events are collected through the end of the study.

Statistical Analysis

No formal statistical hypothesis was tested in this study, and all results were descriptive.

Study Results

The study showed a dose response in participants across all age groups as measured by both binding and neutralizing antibodies after 2 doses. There was a comparable response between the 100-µg and 250-µg dose groups, and both were greater compared to the 25-µg group. The bAb and nAb levels seen after 2 doses of 100 µg or 250 µg of mRNA-1273 were similar in magnitude compared to those seen in pooled convalescent sera from patients recovered from COVID-19. All dose levels elicited CD4+ T-cell responses that were strongly biased toward expression of Th1 cytokines, with minimal Th2 cytokine expression. This Th1-dominant profile was clinically reassuring in terms of risk of developing vaccine-induced disease. These results, along with the interim safety data showing a lower incidence of reactogenicity in the 100ug group compared to the 250ug group, led to the selection of the 100ug dose to advance to Phase 2 and 3. Preliminary safety data from this Phase 1 study show a similar profile to that observed in the Phase 3 study. No SAEs or severe COVID-19 cases have been reported from this study as of November 16, 2020.

Study mRNA-1273-P201

Study Design
Study mRNA-1273-P201 is an ongoing phase 2a, randomized, observer-blind, placebo-controlled, dose-confirmation study to evaluate the safety, reactogenicity, and immunogenicity of mRNA-1273 in healthy adults 18 years and older. The study enrolled 600 participants, consisting of 300 participants 18 to <55 years old and 300 participants 55 years and older, who

were randomized equally to receive either 2 doses of 50ug of mRNA-1273, 100ug of mRNA-1273, or saline placebo given 28 days apart. Participants will be followed for safety and immunogenicity for 12 months post last vaccination.

Study Objectives/Endpoints Relevant to the EUA
The immunogenicity objectives are to evaluate the immunogenicity of 2 doses of mRNA-1273 at the 2 dose levels (50 µg and 100 µg) administered 28 days apart as assessed by level of bAb and by nAb titers at baseline and at various time points after vaccination. All participants are followed for solicited adverse reactions through 7 days post each vaccination. Unsolicited AEs are collected through 28 days after each vaccination. All SAEs and medically attended adverse events are collected through the end of the study.

Statistical Analysis

No formal statistical hypothesis was tested in this study and all results were descriptive.

Study Results

The immune response as assessed by bAb and nAb after 2 doses were comparable in the 50-µg and 100-µg dose groups, with an overall geometric mean fold rise (GMFR)>20-fold in bAB as measured by ELISA and >50-fold in nAb as measured by microneutralization assay at 28 days post-dose 2. In the 100-µg dose group, the older age cohort (≥55 years) had slightly lower bAb response when compared to the younger age cohort (18 to <55 years) at 28 days post-dose 2, but the nAb response was similar between both age groups

Safety profile was similar to that reported in the Phase 3 study. Laboratory evaluations (including complete blood count, liver function tests, kidney functions tests, and coagulation studies) were conducted for participants ≥55 years of age (N=100) at baseline and at 1 month after the second dose (Day 29, Day 57). According to narratives that the Sponsor provided to FDA on December 6, 2020, there were 2 participants in the 100-µg group who experienced Grade 3 decreases in hemoglobin (Grade 0 reported at baseline), but both Grade 3 values were within normal range and not clinically significant. The overall event rates were not provided.

As of December 6, 2020, there were 3 SAEs reported in the vaccine group: a 65-year-old participant with community acquired pneumonia 25 days after vaccination, a 72-year-old participant with arrhythmia after being struck by lightning 28 days after vaccination, and an 87-year-old participant with worsening of chronic bradycardia 45 days after vaccination. On FDA review of the narratives, none of these SAEs are assessed as related. There were no cases of severe COVID-19 reported in the study.

1 COMPLIANCE STATEMENT

Study Title: A Tissue Distribution Study of a [^{3}H]-Labelled Lipid Nanoparticle-mRNA Formulation Containing ALC-0315 and ALC-0159 Following Intramuscular Administration in Wistar Han Rats

GLP regulations are not applicable to studies of this nature therefore no claim of GLP compliance is made. Nevertheless, as Study Director, I confirm that this study was conducted in a GLP compliant facility and that the practices and procedures adopted during its conduct were consistent with the OECD Principles of Good Laboratory Practice as incorporated into the United Kingdom Statutory Instrument for GLP.

The study was conducted according to the procedures herein described and this report represents a true and accurate record of the results obtained.

4 SUMMARY

The test item, 08-A01-C01, is an aqueous dispersion of lipid nanoparticles (LNP), comprised of a proprietary mixture of lipid components (including ALC-0315, ALC-0159, distearoylphosphatidylcholine, and cholesterol) and mRNA. The mRNA encodes a model protein (luciferase) and is not pharmacologically active. The test item contains trace amounts of radiolabelled [Cholesteryl-1,2-^{3}H(N)]-Cholesteryl Hexadecyl Ether ([^{3}H]-CHE), a non-exchangeable, non-metabolisable lipid marker used to monitor the disposition of the lipid nanoparticles (containing encapsulated mRNA). Once intracellular, the [^{3}H]-CHE does not recirculate and therefore allows assessment of distribution of the particles.

The objectives of this study were to:

1. Characterise the disposition of 08-A01-C01 containing a radiolabelled lipid marker in male and female Wistar Han rats following a single intramuscular administration.

2. Determine the concentration and content of radioactivity in blood, plasma and tissues of rats (expressed as µg lipid eq/mL (or per g for tissue), and % administered (injected dose)/tissue, where appropriate).

Wistar Han rats (21 male and 21 female) each received a single intramuscular dose of [^{3}H]-08-A01-C01 at a target mRNA total dose of 50 µg/animal (1.29 mg/animal total lipid dose). The content and concentration of total radioactivity in blood, plasma and tissues were determined at pre-defined time points following administration.

Whole blood and tissue samples were collected at 0.25 1, 2, 4, 8, 24 and 48 hours post-dose (three animals/sex/timepoint) and plasma was subsequently separated from blood by centrifugation. The concentration of total radioactivity was measured by liquid scintillation counting (LSC).

Following intramuscular administration of [^{3}H]-08-A01-C01 to male and female Wistar Han rats at a target dose level of 50 µg/animal (1.29 mg/animal total lipid dose), the greatest mean concentration was found remaining in the injection site at each time point in both sexes. Outside the injection site, low levels of radioactivity were detected in most tissues, with the greatest levels in plasma observed 1-4 hours post-dose. Over 48 hours, [^{3}H]-08-A01-C01 distributed mainly to liver, adrenal glands, spleen and ovaries, with maximum concentrations observed at 8-48 hours post-dose. Total recovery (% of injected dose) of [^{3}H]-08-A01-C01 outside the injection site was greatest in the liver (up to 21.5%) and was much less in spleen (≤1.1%), adrenal glands (≤0.1%) and ovaries (≤0.1%). The mean concentrations and tissue distribution pattern were broadly similar between the sexes.

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

Blood:plasma ratios were generally between 0.5-0.6, indicating that the majority of the total radioactivity is associated with the plasma fraction and that [^{3}H]-08-A01-C01 does not undergo appreciable accumulation in red blood cells.
In conclusion, the distribution of [^{3}H]-08-A01-C01 (monitoring the [^{3}H]-CHE lipid label) in blood, plasma and selected tissues was determined in male and female Wistar Han rats over 48 hours after a single intramuscular injection at 50 µg mRNA/animal (1.29 mg/animal lipid dose). The concentrations of [^{3}H]-08-A01-C01 were greatest in the injection site at all time points, with levels peaking in the plasma by 1-4 hours post-dose and distribution mainly into liver, adrenal glands, spleen and ovaries over 48 hours. Total recovery of radioactivity outside of the injection site was greatest in the liver, with much lower total recovery in spleen, and very little recovery in adrenals glands and ovaries. The mean plasma, blood and tissue concentrations and tissue distribution patterns were broadly similar between the sexes and [^{3}H]-08-A01-C01 did not associate with red blood cells.

5 INTRODUCTION

The objectives of this study were to:

1. Characterise the disposition of 08-A01-C01 containing a radiolabelled lipid marker in male and female Wistar Han rats following a single intramuscular administration

2. Determine the concentration and content of radioactivity in blood, plasma and tissues of rats (expressed as µg lipid eq/g (or per mL for plasma) and % injected dose/tissue, where appropriate)

The Wistar Han rat was chosen as the animal model for this study as it is an accepted rodent species for preclinical toxicity testing by regulatory agencies and has been used in all regulatory toxicology studies by the Sponsor.

The study was designed to be appropriate for submission to regulatory authorities. However, it is recognised that no detailed test guidelines for the conduct of drug distribution and pharmacokinetic studies are currently available.

Initially, 21 male rats were dosed at 100 µg mRNA/animal. Some adverse clinical signs were observed after approximately 24 hours post-dose and a subsequent review of the data showed concentrations were well detected in tissues. After discussions with the Sponsor, the target dose level was lowered to 50 µg mRNA/animal by amendment for the remainder of the study. Reference is made to the 100 µg mRNA /animal group in some sections of the report, however, the results are not discussed.

5.1 Study Location

The study was carried out at (b) (4) (b) (4) according to (b) (4) Protocol No. 185350 and Amendments 1 and 2.

5.2 Study Dates The study was conducted according to the following timetable:

Study Initiation:	16 July 2020
Experimental Start Date:	17 July 2020
Experimental Completion Date:	24 September 2020
Study Completion Date:	See compliance page for date of Study Director's signature.

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

5.3 Archiving

All raw data generated and recorded during this study will be stored in the Scientific Archive of (b) (4) for 2 years after issue of the final report. After the 2-year period the Sponsor will be consulted regarding the disposal, transfer, or continued storage of the raw data. Electronic data generated by the Test Facility were archived as noted above, except reporting files stored on Shared Document Management System (SDMS), which were archived at the (b) (4)

The original signed copy of the final report will be stored indefinitely in the Scientific Archive of (b) (4)

The residual [^{3}H]-08-A01-C01 dose (approximately 5 MBq) will be retained and stored in a fridge set to maintain 4°C at (b) (4)

Biological samples generated during the course of this study were held deep frozen until issue of the final report. (b) (4) will contact the Sponsor to discuss the fate of the samples (disposal, return or retain at (b) (4)) on issue of the final report. Samples will be disposed of unless (b) (4) receives written instruction regarding shipment of the samples to the Sponsor or continued storage at (b) (4)

6 EXPERIMENTAL PROCEDURE

6.1 Test Item

Identification:	[^{3}H]-08-A01-C01
Supplier:	Acuitas Therapeutics Inc
Lot Number:	NC-0552-1
Expiration Date:	July 7, 2021
Physical Description:	White to off-white, homogenous, opalescent liquid; no foreign particles
Concentration (mRNA):	1.0 mg/mL
Radioactive Concentration	0.864 mCi/mL, 1,900,000 dpm/µL

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

Concentration (Total Lipid)	25.7 mg/mL
Molecular weight	Not applicable for LNP
Purity:	94%
Radiochemical Purity	>97%
Specific Activity (mRNA):	0.864 mCi/mg (32.0 MBq/mg)
Correction Factor	None
Storage Conditions:	Frozen (-60°C to -90°C)

The test item contains trace amounts of radiolabelled [Cholesteryl-1,2-^{3}H(N)]-Cholesteryl Hexadecyl Ether ([^{3}H]-CHE), a non-exchangeable, non-metabolisable lipid marker used to monitor the disposition of the lipid nanoparticles (containing encapsulated mRNA). Per the manufacturer's information, the radiochemical purity of [^{3}H]-CHE was found to be >97% and the rate of decomposition is initially 2% for 6 months from the date of purification (16 December 2019). No radiochemical purity assessments were made as part of this study.

The Certificates of Analysis for [^{3}H]-08-A01-C01 and [^{3}H]-CHE are presented in Appendix 1

6.2 Other Materials

AquaSafe 500 Plus liquid scintillation fluid was obtained from Zinsser Inc.

Monophase® was used in conjunction with the Perkin Elmer Model 307 Automatic Sample Oxidiser and was supplied by Perkin Elmer Life Science and Analytical Instruments Inc, UK.

Spec-Chec™-^{3}H used to estimate efficiencies of combustion was also obtained from Perkin Elmer Life Science and Analytical Instruments Inc, UK.

All other materials and chemicals used were of analytical grade where available and supplied by standard commercial suppliers.

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

6.3 Animals and Husbandry

Forty-two male and 21 female Wistar Han rats (8-11 weeks and body weight 179-270 g at the time of dosing) were used in the study and were supplied by [redacted]. The animals were acclimatised to the experimental unit for at least 5 days prior to use on the study. During the acclimatisation periods, the animals were closely observed by the animal technicians to ensure that they were in good health and suitable for inclusion in the study. During the study period the animals were closely observed twice daily by the animal technicians to ensure that they were in good health.

During the study period, the rats were housed in groups in polycarbonate and stainless steel cages with wire mesh floors. Animals used for excretion collection were housed singly in all-glass metabolism cages for the separate collection of urine and faeces.

A standard laboratory diet of known formulation (SDS Rat and Rat Maintenance Diet No.1, Special Diet Services, 1 Stepfield, Witham, Essex) and domestic mains tap water were available *ad libitum*.

Holding and study areas had automatic control of light cycles and temperature. Automatic 12 hours light and 12 hours dark. Ranges of temperature and humidity measured during the study were 21-23°C and 44-67%, respectively, with the exception of 31 July 2020 where the room temperature reached a maximum of 25°C.

6.4 Specific Activity

The specific activity value of 1.24 MBq/mg lipid (as calculated from the 0.864 mCi/mg mRNA specific activity value supplied and converted to per mg lipid) was used to calculate the amount of [^{3}H]-08-A01-C01 dispensed in the dose formulation.

6.5 Dose Formulation

[^{3}H]-08-A01-C01 was provided in PBS/sucrose buffer at the required dose concentration (1 mg mRNA/mL). No dilutions were therefore required. Four dose formulation vials were provided (3 x 1.5 mL and 1 x 1.2 mL).

The appropriate number of vials for each dosing occasion were defrosted for at least 30 minutes prior to dosing. Prior to use, each vial was inverted 3 times to mix. Once dosing was complete, each vial was stored in a fridge within 4 hours of removal from the -80°C freezer.

The radioactive concentration of the supplied dose formulation was determined by the removal of triplicate aliquots (50 µL) prior to and after the first dosing occasion. Appropriate

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

dilutions of each aliquot were prepared in distilled water and duplicate aliquots of each dilution were analysed by liquid scintillation counting (LSC).

The radioactive concentration determined by LSC was within 10% of the target value provided in the supplied Certificate of Analysis and was used in the dose determination calculations.

6.6 Dose Administration and Determination

Each animal received a single (one site) intramuscular administration of [^{3}H]-08-A01-C01 at either 50 or 100 µL volume for the 50 and 100 µg mRNA/animal dose groups, respectively (target doses of 1.29 or 2.57 mg total lipid/animal, respectively).

The actual dose received by each animal was determined with reference to the dose concentration, the volume of dose administered and the specific activity of [^{3}H]-08-A01-C01 in the formulated dose. Any undosed residue was also taken in to account. The actual dose received by each animal is documented in Appendix 2.

6.7 Collection of Biological Samples

Three male and three female rats were sacrificed at the following times:

0.25, 1, 2, 4, 8, 24 and 48 hours post dose

From each animal, a terminal blood sample (*ca.* 5-10 mL) was collected by cardiac puncture into heparinised tubes. A portion (*ca.* 0.5 mL) was retained and plasma separated from the remainder of each sample by centrifugation (3000 rpm for 10 minutes in a centrifuge set to maintain a temperature of 4°C). Blood cells were discarded.

The following tissues were collected (where relevant for sex)

Adipose tissue	Ovaries
Adrenal glands	Pancreas
Bladder	Pituitary gland
Bone (femur)	Prostate
Bone marrow (femur)	Salivary glands
Brain	Skin
Eyes	Muscle
Heart	Small intestine
Injection site	Spinal cord
Kidneys	Spleen
Large intestine	Stomach
Liver	Testes
Lung	Thymus
Lymph node (mandibular)	Thyroid

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

Lymph node (mesenteric)	Uterus

Additionally, for animals 043M, 045M, 046M, 048M, 051M, 052M, 055M and 058M, the tibia/fibula bone was also collected but not analysed (refer to Section 6.11).

6.8 Sample Storage

Samples not analysed immediately were stored frozen in a freezer set to maintain a temperature of -20°C until taken for analysis, with the exception of urine and faeces samples which were stored at -80°C. After analysis, samples were returned to storage in a freezer set to maintain a temperature of -20°C.

Samples of cage wash, dose determinations and dose residues were stored at room temperature prior to and following analysis. These samples were discarded at the Study Director's discretion following acceptance of the study results.

6.9 Preparation of Samples for Total Radioactivity Analysis

Volumes or weights of all samples were measured where appropriate

6.9.1 Dose Formulation

Duplicate aliquots (0.1 mL) of each dilution of the dose formulation were diluted with water and dissolved in scintillation fluid (Aquasafe 500 Plus, Zinsser Inc.) and analysed directly by liquid scintillation counting.

6.9.2 Blood and Plasma

Duplicate weighed aliquots of whole blood (2 x *ca.* 0.15 g) were taken and then combusted using a Perkin Elmer Model 307 Sample Oxidiser. The resultant $^{3}H_2O$ generated was collected by absorption in Monophase® (15 mL).

Duplicate aliquots (100 µL) of plasma were allowed to air dry, diluted with water and dissolved in scintillation fluid (Aquasafe 500 Plus, Zinsser Inc.) and analysed directly by LSC.

6.9.3 Tissues

Tissue samples were finely chopped with scissors and duplicate, where appropriate, portions were combusted using a Perkin Elmer Model 307 Sample Oxidiser. Smaller tissues were aliquoted directly. The resultant $^{3}H_2O$ generated was collected by absorption in Monophase® S (15 mL).

Combustion of standards showed that recovery efficiencies were in excess of 95% throughout.

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

6.9.4 Urine, Faeces and Cage Wash

Urine, faeces and cage wash samples were collected but not analysed for total radioactivity. Urine and faeces sample weights were taken prior to storage. Urine and faeces samples were retained at -80°C for possible analysis of specific lipids by LC-MS/MS conducted and reported separately. The sample weights are presented in Appendix 3.

6.10 Quantification of Radioactivity

6.10.1 Liquid Scintillation Counting

All samples prepared in scintillation fluid were subjected to liquid scintillation counting for 5 min, together with representative blank samples, using a Liquid Scintillation Analyser with automatic quench correction by an external standard method. Prior to analysis, samples were allowed to stabilise with regard to light and temperature. Self-normalisation and calibration (SNC) were conducted once a day. An unquenched tritium standard was used to initially calibrate the system to obtain optimal performance by adjusting the voltage on the photo-multiplier tubes. Representative blank sample values were subtracted from sample count rates to give net disintegrations per minute (dpm) per sample. A limit of reliable measurement of 30 counts per minute (cpm) above background was instituted in these laboratories. Any results arising from data below the limit of reliable measurement were noted in the Results section of the report. Sample repeat analysis were in accordance with Standard Operating Procedures.

6.10.2 Data Presentation

Levels of radioactivity in all samples were quantified by LSC and the data captured into DEBRA® management software, Version 5.7 (LabLogic Ltd, UK). Plasma, blood and tissues concentrations of radioactivity in dpm/g and mass eq/g were calculated based on the measured specific activity (1.24 MBq/mg lipid) of radiolabelled test item in the dose formulation.

Individual and mean data were tabulated. The following information was reported:

- Radioactive content in tissues where a total organ weight is applicable was calculated as % administered (injected) dose
- Radioactive content in tissues, whole blood and plasma as µg equiv/g (or mL).
- Blood/plasma ratio

Data presented in results tables are computer generated in DEBRA and rounded appropriately for inclusion in the report. As a consequence, calculation of individual and mean values from data presented will, in some instances, yield slight differences from the results presented.

6.11 Protocol Deviations

Due to the unavailability of rats within specification at [redacted] the rat supplier used in this study was Envigo, UK, deviating from Section 11 of the Protocol. In the opinion of the Study Director this had no impact on the study outcome since the correct age and strain of rats were used on this study.

In error, tibia/fibula bone were collected at necropsy for animals 043M, 045M, 046M, 048M, 051M, 052M, 055M, and 058M instead of femur bone, deviating from Section 14.1 of the Protocol. Once noticed, the femur bone was retrieved from the residual carcass stored in the -20°C freezer pending disposal and analysed after discussions with the Sponsor. The results appeared similar to the other animals in each timepoint and therefore this had no impact on the study outcome.

7 RESULTS

7.1 Clinical Observations

In the 100 µg mRNA male group, approximately 24 h following administration, animal 021M was noted to have decreased activity, ungroomed, brown staining on muzzle and irregular respiration. A decrease in bodyweight was noted in all remaining animals (approximately 16 g, equivalent to *ca.* 7% reduction of bodyweight) and food hoppers appeared untouched. By approximately 30 hours post-dose, animal 021M was also piloerect, hunched, and was hypersensitive to noise stimulus. Animal 021M was humanely killed and the diagnostic necropsy carried out showed one finding in the liver (prominent lobular architecture). Additionally, animals 019M and 020M were hunched and piloerect from approximately 30 h post-dose onwards.

In the 50 µg mRNA male group, following administration and for the duration of the study, no adverse effects were noted in any animal.

In the 50 µg mRNA female group, approximately 30 h following administration, animal 042F was noted to have decreased activity, and irregular respiration. At 48 h post dose animal 042F was additionally hunched and piloerect.

7.2 Body Weights

At the time of dosing, body weights were in the range of 217-270 g (males) and 179-224 g (females).

7.3 Tissue Distribution Following Intramuscular Administration

The mean (sex combined) concentration and recovery of total radioactivity in whole blood, plasma, injection site and tissues following a single intramuscular administration of [^{3}H]-08-A01-C01 to Wistar Han rats at a target dose level of 50 µg mRNA/animal (1.29 mg/animal lipid) is presented in Table 1. The mean concentration of total radioactivity in whole blood, plasma, injection site and tissues following a single intramuscular administration of [^{3}H]-08-A01-C01 to male and female Wistar Han rats at a target dose level of 50 µg mRNA/animal (1.29 mg/animal lipid) is presented in Table 2. The mean recovery in male and female individual tissues is presented in Table 3.

Individual male and female concentration data is presented in Appendix 4 and Appendix 5, respectively. Individual male and female recovery data is presented in Appendix 6 and Appendix 7, respectively. The male 100 µg data is presented in Appendix 8.

When analysing the injection site, there was often high inter-animal variability in concentration and % injected dose values at each time point. This may have been due to

090177e195794698\Approved\Approved On: 09-Nov-2020 21:23 (GMT)

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

difficulty in collecting the entirety of this sample since the total area that the injected bolus dose migrated to within the muscle was not visible. When dosing the male 50 µg mRNA group, the injection site was circled using a marker pen to help aid dissection of the injection area. The overall injection site concentrations and % dose values were higher in males than in females. Since concentrations in other tissues were broadly similar between the sexes, it is likely that the higher injection site values in males were a result of its more consistent identification and collection in males.

Following a single intramuscular administration of [^{3}H]-08-A01-C01, the greatest mean tissue concentration and, in most instances, % of injected dose was found remaining in the injection site at each time point in both sexes. The injection site mean concentration and equivalent % dose values are presented in the table below.

Timepoint (h)	Injection site (µg equiv lipid/g)		Injection site (% dose)	
	Male	Female	Male	Female
0.25	219.940	36.566	32.887	6.815
1	587.670	199.950	68.829	36.411
2	529.210	93.144	39.053	24.094
4	619.850	56.227	47.710	9.056
8	299.590	125.930	18.731	24.993
24	267.170	122.540	31.957	26.295
48	268.770	61.088	32.823	16.426

The highest mean recovery of total radioactivity observed was 68.8% of the administered dose at 1-hour post-dose in males.

Low levels of radioactivity were detected in most tissues from the first time point (0.25 h), with the greatest level found circulating in plasma between 1-4 hours post-dose. The plasma and blood mean concentrations and blood:plasma ratios are presented in the table below.

Timepoint (h)	Blood (µg equiv lipid/g)		Plasma (µg equiv lipid/mL)		Blood:plasma ratio	
	Male	Female	Male	Female	Male	Female
0.25	3.003	0.936	6.035	1.894	0.48	1.15
1	2.809	5.928	5.379	10.884	0.49	0.54
2	4.028	6.773	8.714	9.091	0.46	0.64
4	3.400	2.698	8.755	4.251	0.42	0.60
8	2.000	0.628	3.573	1.147	0.56	0.55
24	1.274	0.544	2.621	0.945	0.49	0.57
48	0.535	0.305	1.085	0.524	0.50	0.58

Mean plasma concentrations peaked by 4 hours post-dose in males (8.755 µg equiv lipid/mL) and by 1 hour post-dose in females (10.884 µg equiv lipid/mL), before steadily decreasing. Concentrations were higher in plasma than in blood, with mean blood:plasma ratios generally

ca. 0.5-0.6, indicating that the majority of the total radioactivity is associated with the plasma fraction.

Over 48 hours, [^{3}H]-08-A01-C01 distributed from the injection site to most tissues, with the majority of tissues exhibiting low levels of radioactivity. The highest mean concentrations observed, and the equivalent % dose, are presented in the tables below.

Timepoint (h)	Values expressed as µg equiv lipid/g)

=Mean includes results calculated from data less than 30 cpm above background

Maximum concentrations (C_{max}) in liver and spleen were observed at 8 hours post-dose in males and 48 hours post dose in females, but were broadly similar and appeared to plateau at 8 hours post-dose when considering variability. The greatest mean concentration outside the injection site was observed in the liver, with values of 27.916 µg equiv lipid/g (equivalent to 21.5 % dose) in males and 30.411 µg equiv lipid/g (equivalent to 18.4 % dose) in females. In the spleen the highest concentrations were 24.434 µg equiv lipid/g in males and 27.155 µg equiv lipid/g (equivalent to 1.1% dose in both sexes).

In the adrenal glands and ovaries, the highest mean concentrations were observed at 48 hours post-dose. The highest mean concentrations in the adrenal glands were 21.476 and 14.942 µg equiv lipid/g in males and females, respectively (equivalent to 0.1% dose in both sexes). The highest mean ovaries concentration was 12.261 µg equiv lipid/g (equivalent to 0.1 % dose).

8 CONCLUSIONS

In conclusion, the distribution of [^{3}H]-08-A01-C01 (monitoring the [^{3}H]-CHE lipid label) in blood, plasma and selected tissues was determined in male and female Wistar Han rats over 48 hours after a single intramuscular injection at 50 µg mRNA/animal (1.29 mg/animal lipid dose). The concentrations of [^{3}H]-08-A01-C01 were greatest in the injection site at all time points, with levels peaking in the plasma by 1-4 hours post-dose and distribution mainly into liver, adrenal glands, spleen and ovaries over 48 hours. Total recovery of radioactivity outside of the injection site was greatest in the liver, with much lower total recovery in spleen, and very little recovery in adrenals glands and ovaries. The mean plasma, blood and tissue concentrations and tissue distribution patterns were broadly similar between the sexes and [^{3}H]-08-A01-C01 did not associate with red blood cells.

Notes

Formulated July 6, 2020 for NC-0552 using BioNTech mRNA (AnSo luc 1041 CorVac) and trace labeled with 3H-CHE. Endotoxin below detection limit (<0.5 EU/mL). Sterile filtered using 0.2 µm pore-size filters.

Stored at -70°C. Thaw at room temperature and dilute on the day of use.

TECHNICAL DATA SHEET ^{3}H

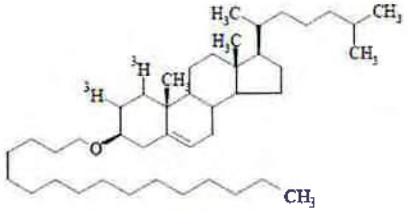
Research Use Only. Not for use in diagnostic procedures

CHOLESTERYL HEXADECYL ETHER, [CHOLESTERYL-1,2-^{3}H(N)]-

Product Number: NET859

LOT SPECIFIC INFORMATION

Lot Number:	2656317	
Specific Activity:	51.9	Ci/mmol
	1920	GBq/mmol
Production Date:	16-Dec-2019	



M.W. 611.1
$C_{43}H_{78}O$

PACKAGING: 1.0 mCi/ml (37 MBq/ml) in toluene, under argon in an ampoule. Shipped on dry ice.

STABILITY AND STORAGE RECOMMENDATIONS: When cholesteryl hexadecyl ether, [cholesteryl-1,2-^{3}H(N)]- is stored at -20°C in its original solvent and at its original concentration, the rate of decomposition is initially 2% for 6 months from date of purification. Stability is nonlinear and not correlated to isotope half-life. Lot to lot variation may occur.

SPECIFIC ACTIVITY RANGE: 40-60 Ci/mmol (1480-2220 GBq/mmol)

RADIOCHEMICAL PURITY: This product was initially found to be greater than 97% when determined by the following methods. The rate of decomposition can accelerate. It is advisable to check purity prior to use:

High pressure liquid chromatography on a Zorbax C-8 column using the following mobile phase:
acetonitrile : isopropanol, (35:65).

Thin layer chromatography on silica gel using the following solvent system:
toluene : hexane, (1:9).

QUALITY CONTROL: The radiochemical purity of cholesteryl hexadecyl ether, [cholesteryl-1,2-^{3}H(N)]- is checked at appropriate intervals using the first listed chromatography method.

The precursor used in the synthesis of NET-859 is synthetic.

HAZARD INFORMATION: WARNING: This product contains a chemical known to the state of California to cause cancer.

Appendix 7 (continued) **Individual Female Recovery Data**

Recovery of Total Radioactivity in Tissues 48 hours Following Single Intramuscular Administration of [^{3}H]-08-A01-C01 to Female Wistar Han Rats

Target Dose Level: 50 µg mRNA/Animal; 1.29 mg Total Lipid/Animal

Results expressed as % administered dose

LIST OF FIGURES

本項で使用する用語・略語

用語・略号	省略していない表現または定義
ALC-0159	本剤に添加される PEG 脂質
ALC-0315	本剤に添加されるアミノ脂質
[^{3}H]-CHE	Radiolabeled [Cholesteryl-1,2-^{3}H(N)]-Cholesteryl Hexadecyl Ether：放射性標識 ［コレステリル-1, 2-^{3}H(N)］ヘキサデシルエーテル
DSPC	1,2-distearoyl-sn-glycero-3-phosphocholine：1,2-ジステアロイル-sn-グリセロ-3-ホスホコリン
GLP	Good Laboratory Practice：医薬品の安全性に関する非臨床試験の実施の基準
LNP	Lipid-nanoparticle：脂質ナノ粒子
modRNA	Nucleoside-modified mRNA：修飾ヌクレオシド mRNA
mRNA	Messenger RNA：メッセンジャーRNA
m/z	m/z（m・オーバー・z）：イオンの質量を統一原子質量単位（＝ダルトン）で割って得られた無次元量をさらにイオンの電荷数の絶対値で割って得られる無次元量
PEG	Polyethylene glycol：ポリエチレングリコール
PK	Pharmacokinetics：薬物動態
RNA	Ribonucleic acid：リボ核酸
S9	Supernatant fraction obtained from liver homogenate by centrifuging at 9000 g：肝ホモジネートを 9000 g で遠心分離した上清画分
WHO	World Health Organization：世界保健機関

1. まとめ

BNT162b2（BioNTech コード番号：BNT162，Pfizer コード番号：PF-07302048）は，重症急性呼吸器症候群コロナウイルス 2（SARS-CoV-2）のスパイク糖タンパク質（S タンパク質）全長体をコードする修飾ヌクレオシド mRNA（modRNA）であり，SARS-CoV-2 による感染症に対する mRNA ワクチンの本質として開発が進められている。BNT162b2 の製剤化にあたっては，2 つの機能脂質である ALC-0315（アミノ脂質）および ALC-0159（PEG 脂質）ならびに 2 つの構造脂質として DSPC（1,2-distearoyl-sn-glycero-3-phosphocholine）およびコレステロールと混合することで BNT162b2 を封入する脂質ナノ粒子（LNP）が形成される（以降，「BNT162b2 封入 LNP」）。

BNT162b2 封入 LNP の非臨床薬物動態を評価するために，LNP に含まれる ALC-0315 および ALC-0159 の吸収（PK），代謝および排泄を評価する in vivo および in vitro 試験ならびに BNT162b2 の代替レポーターとしてルシフェラーゼまたは放射能標識した脂質を利用した生体内分布試験を実施した。

感染症予防を目的としたワクチンの開発では全身曝露量の評価を必要としないことを踏まえ（WHO, 2005；感染症予防ワクチンの非臨床試験ガイドライン）[1,2]，BNT162b2 封入 LNP の筋肉内投与による PK 試験は実施しなかった。また，本剤に含有される他の 2 種類の脂質（コレステロールおよび DSPC）は天然に存在する脂質であり，内在性脂質と同様に代謝，排泄されると考えられる。加えて，BNT162b2 は取り込んだ細胞中のリボヌクレアーゼにより分解されて核酸代謝され，BNT162b2 由来の S タンパク質はタンパク分解を受けると予想される。以上のことから，あらためてこれらの成分の代謝および排泄を評価する必要はないと考えられた。

BNT162b2 の代替レポーターとしてルシフェラーゼをコードする RNA を封入した LNP（ルシフェラーゼ RNA を BNT162b2 封入 LNP と同一の脂質構成を持つ LNP に封入：以降，「ルシフェラーゼ RNA 封入 LNP」）を Wistar Han ラットに静脈内投与した PK 試験では，血漿，尿，糞および肝臓試料を経時的に採取して，各試料中の ALC-0315 および ALC-0159 濃度を測定した。その結果，ALC-0315 および ALC-0159 は血中から肝臓にすみやかに分布することが示された。また，ALC-0315 および ALC-0159 はそれぞれ投与量の約 1%および約 50%が未変化体として糞中に排泄され，尿中においてはいずれも検出限界未満であった。

生体内分布試験では，ルシフェラーゼ RNA 封入 LNP を BALB/c マウスに筋肉内投与した。その結果，ルシフェラーゼの発現が投与部位でみられ，それより発現量は低値であったものの肝臓でも認められた。ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現も投与後 6 時間に認められ，投与後 48 時間までに消失した。また，ルシフェラーゼ RNA 封入 LNP の放射能標識体をラットに筋肉内投与して生体内分布を定量的に評価したところ，放射能濃度は投与部位で最も高値であった。投与部位以外では肝臓が最も高かった（投与量の最大 18%）。

ALC-0315 および ALC-0159 の代謝を CD-1/ICR マウス，Wistar Han または Sprague Dawley ラット，カニクイザルもしくはヒトの血液，肝ミクロソーム，肝 S9 画分および肝細胞を用いて in vitro で評価した。また，上記のラット静脈内投与 PK 試験で採取した血漿，尿，糞および肝臓試料を用いて in vivo 代謝についても検討した。これら in vitro および in vivo 試験から，ALC-0315 および ALC-0159 は，試験したいずれの動物種でも，それぞれエステル結合およびアミド結合の加水分解により緩徐に代謝されることが示された。

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

以上の非臨床薬物動態評価より，循環血中に到達した LNP は肝臓に分布することが示された。また，ALC-0315 および ALC-0159 の消失には，それぞれ代謝および糞中排泄が関与することが示唆された。

2. 分析法

報告書番号：PF-07302048_06[redacted]_072424

GLP 非適用のラット静脈内投与 PK 試験（M2.6.4.3 項）で LNP の構成脂質である ALC-0315 および ALC-0159 濃度を定量するために適切な性能を有する LC/MS 法を開発した。すなわち，20 µL の血漿，肝ホモジネート（肝臓の 3 箇所から採取した切片を用いてホモジネートを調製し，それらをプールしたものを適宜，ブランクマトリクスで希釈），尿および糞ホモジネート（適宜，ブランクマトリクスで希釈）試料をそれぞれ内部標準物質（PEG-2000）を含有するアセトニトリルで除タンパクした後，遠心分離し，その上清を LC-MS/MS 測定に供した。

3. 吸収

報告書番号：PF-07302048_06[redacted]_072424，概要表：2.6.5.3

ALC-0315 および ALC-0159 の体内動態を検討するため，ルシフェラーゼ RNA 封入 LNP を雄性 Wistar Han ラットに 1 mg RNA/kg の用量で単回静脈内投与し，経時的（投与前，投与後 0.1，0.25，0.5，1，3，6 および 24 時間ならびに投与後 2，4，8 および 14 日）に血漿および肝臓をスパースサンプリングにより採取（3 匹/時点）した。血漿中および肝臓中の ALC-0315 および ALC-0159 濃度を測定し，PK パラメータを算出した（Table 1）。血中の ALC-0315 および ALC-0159 は，投与後 24 時間までにすみやかに肝臓へ分布した。また，投与後 24 時間の血漿中濃度は最高血漿中濃度の 1%未満であった（Figure 1）。見かけの終末相消失半減期（t½）は血漿中および肝臓中で同程度で，ALC-0315 は 6～8 日，ALC-0159 は 2～3 日であった。本試験の結果から，肝臓が血中からの ALC-0315 および ALC-0159 を取り込む主要組織の 1 つであることが示唆された。

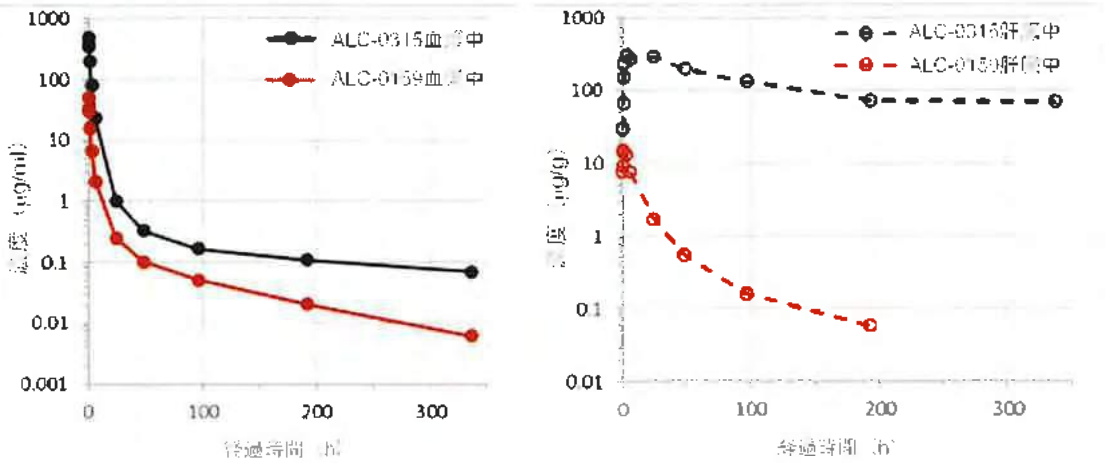
本試験において実施した ALC-0315 および ALC-0159 の尿中および糞中濃度の検討結果については M2.6.4.6 項で述べる。

Table 1 ルシフェラーゼ RNA 封入 LNP を Wistar Han ラットに 1 mg RNA/kg の用量で静脈内投与したときの ALC-0315 および ALC-0159 の薬物動態

分析物	分析物の投与量 (mg/kg)	性/N	t½ (h)	AUC_{inf} (µg•h/mL)	AUC_{last} (µg•h/mL)	肝臓への分布割合 (%)[a]
ALC-0315	15.3	雄/3[b]	139	1030	1020	60
ALC-0159	1.96	雄/3[b]	72.7	99.2	98.6	20

a. ［最高肝臓分布量 (µg)］/［投与量 (µg)］として算出。
b. 各時点 3 匹。スパースサンプリング。

Figure 1 ルシフェラーゼ RNA 封入 LNP を Wistar Han ラットに 1 mg RNA/kg の用量で静脈内投与したときの ALC-0315 および ALC-0159 の血漿および肝臓中濃度

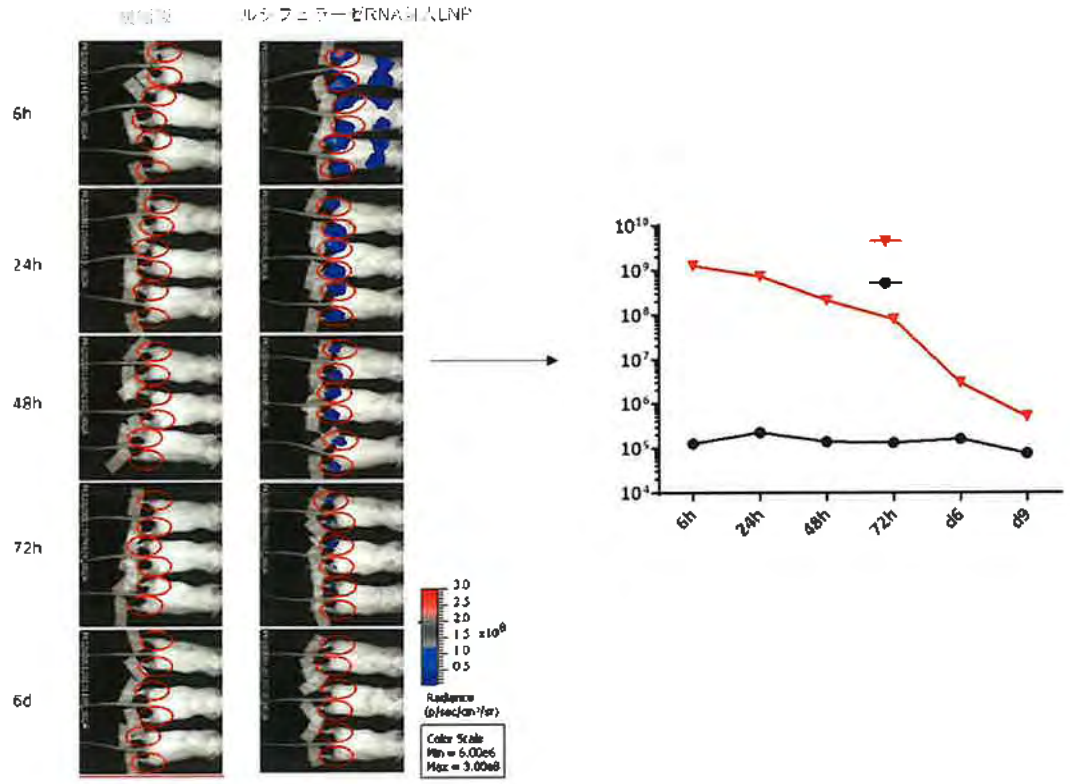


4. 分布

報告書番号：R-[redacted]-0072，185350，概要表：2.6.5.5A，2.6.5.5B

雌性 BALB/c マウス（3 匹）にルシフェラーゼ RNA 封入 LNP を投与し，ルシフェラーゼ発光を代替マーカーとして BNT162b2 の生体内分布を検討した。すなわち，ルシフェラーゼ RNA 封入 LNP をマウスの左右の後肢に各 1 µg RNA（計 2 µg RNA）の用量で筋肉内投与した。その後，ルシフェラーゼ発光検出の 5 分前に発光基質であるルシフェリンを腹腔内投与し，イソフルラン麻酔下，in vivo における発光を Xenogen IVIS Spectrum を用いて投与後 6 および 24 時間ならびに 2，3，6 および 9 日に測定することにより，ルシフェラーゼタンパクの同一個体での経時的な発現推移を評価した。その結果，ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現も投与後 6 時間からみられ，投与後 48 時間までに消失した。肝臓への分布は局所投与したルシフェラーゼ RNA 封入 LNP の一部が循環血中に到達し，肝臓で取り込まれたことを示すものと考えられた。M2.6.4.3 項で詳述したように，ラットにルシフェラーゼ RNA 封入 LNP を静脈内投与した場合には，肝臓が ALC-0315 および ALC-0159 の主要な分布臓器であることが示唆されており，このことはマウスに筋肉内投与した本試験結果の所見と符合するものであった。なお，ラット反復投与毒性試験で肝障害を示す毒性所見は認められていない（M2.6.6.3 項）。

Figure 2 ルシフェラーゼ RNA 封入 LNP を筋肉内投与した BALB/c マウスにおける生体内発光



雌雄 Wistar Han ラットに，[^{3}H]-コレステリルヘキサデシルエーテル（[^{3}H]- CHE）で標識した LNP を用いたルシフェラーゼ RNA 封入 LNP を 50 μg RNA の用量で筋肉内投与し，投与後 15 分ならびに 1，2，4，8，24 および 48 時間の各時点において雌雄各 3 匹から血液，血漿および組織を採取し，液体シンチレーション計数法により放射能濃度を測定することで LNP の生体内分布を評価した。雌雄ともに，放射能濃度はいずれの測定時点においても投与部位が最も高値であった。血漿中の放射能濃度は投与後 1～4 時間で最も高値を示した。また，主に肝臓，脾臓，副腎および卵巣への分布がみられ，これらの組織において放射能濃度が最も高くなったのは投与後 8～48 時間であった。投与部位以外での投与量に対する総放射能回収率は肝臓で最も高く（最大 18%），脾臓（1.0%以下），副腎（0.11%以下）および卵巣（0.095%以下）では肝臓と比較して著しく低かった。また，放射能の平均濃度および組織分布パターンは雌雄でおおむね類似していた。

BNT162b2 がコードする抗原の生体内発現分布は LNP 分布に依存すると考えられる。本試験で用いたルシフェラーゼ RNA 封入 LNP の脂質の構成は，BNT162b2 の申請製剤と同一であることから，本試験結果は BNT162b2 封入 LNP の分布を示すと考えられる。

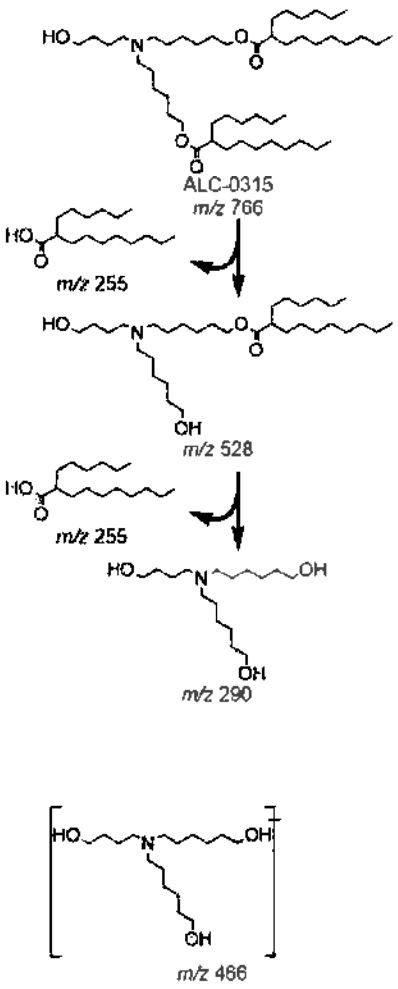
5. 代謝

報告書番号：01049-[redacted]008，01049-[redacted]009，01049-[redacted]010，01049-[redacted]020，01049-[redacted]021，01049-[redacted]022，PF-07302048_05[redacted]_043725，概要表：2.6.5.10A，2.6.5.10B，2.6.5.10C，2.6.5.10D

CD-1/ICR マウス，Wistar Han または Sprague Dawley ラット，カニクイザルならびにヒトの肝ミクロソーム，肝 S9 画分および肝細胞を用いて，ALC-0315 および ALC-0159 の in vitro 代謝安定性を評価した。ALC-0315 または ALC-0159 を各動物種の肝ミクロソームまたは肝 S9 画分（120 分間インキュベーション）もしくは肝細胞（240 分間インキュベーション）に添加して，インキュベーション後の未変化体の割合を測定した。その結果，ALC-0315 および ALC-0159 はいずれの動物種・試験系でも代謝的に安定であり，未変化体の最終的な割合は 82%超であった。

さらに ALC-0315 および ALC-0159 の代謝経路について in vitro および in vivo で評価した。これらの試験では，CD-1 マウス，Wistar Han ラット，カニクイザルおよびヒトの血液，肝 S9 画分および肝細胞を用いて in vitro での代謝を評価した。また，ラット PK 試験で採取した血漿，尿，糞および肝臓試料を用い，in vivo での代謝を評価した（M2.6.4.3 項）。試験結果から，ALC-0315 と ALC-0159 の代謝はいずれも緩徐であり，それぞれエステル結合およびアミド結合の加水分解により代謝されることが明らかになった。Figure 3 および Figure 4 に示した加水分解による代謝は，評価したすべての動物種でみられた。

種　　謝経

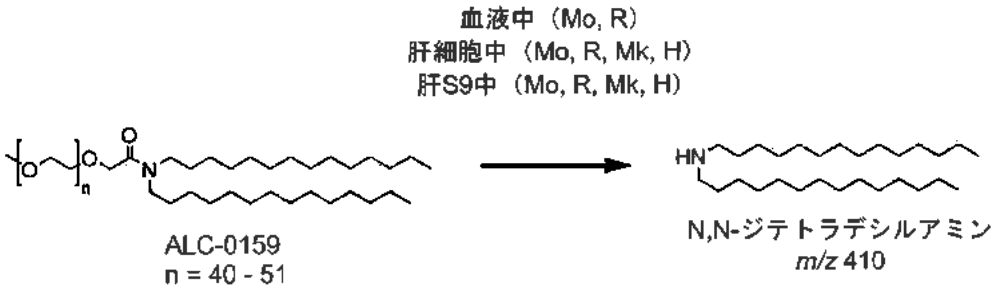


H：ヒト，Mk: サル，Mo：マウス，R：ラット

ALC-0315 はエステル加水分解を 2 回連続で受けることにより代謝される。この 2 回の加水分解により，最初，モノエステル代謝物（*m/z* 528），次に二重脱エステル化代謝物（*m/z* 290）が生成される。この二重脱エステル化代謝物はさらに代謝され，グルクロン酸抱合体（*m/z* 466）となるが，このグルクロン酸抱合体はラット PK 試験で尿中にのみ検出された。また，2 回の加水分解の酸性生成物がいずれも 6-ヘキシルデカン酸（*m/z* 255）であることも確認された。

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

Figure 4 種々の動物種での ALC-0159 の推定生体内代謝経路



H：ヒト，Mk: サル，Mo：マウス，R：ラット

ALC-0159 は，アミド結合の加水分解により *N,N*-ジテトラデシルアミン（*m/z* 410）が生成される経路が主要な代謝経路であった。この代謝物は，マウス・ラットの血液ならびにマウス・ラット・サル・ヒトの肝細胞および肝 S9 画分中に検出された。In vivo 試料からは ALC-0159 の代謝物は確認されなかった。

6. 排泄

ルシフェラーゼ RNA 封入 LNP を 1 mg RNA/kg の用量でラットに静脈内投与した PK 試験（M2.6.4.3 項）で経時的に採取した尿および糞中の ALC-0315 および ALC-0159 濃度を測定した。ALC-0315 および ALC-0159 の未変化体はいずれも尿中に検出されなかった。一方，糞中には ALC-0315 および ALC-0159 の未変化体が検出され，投与量当たりの割合はそれぞれ約 1%および約 50%であった。また，Figure 3 に示したように，ALC-0315 の代謝物が尿中で検出された。

7. 薬物動態学的薬物相互作用

本ワクチンの薬物動態学的薬物相互作用試験は実施していない。

8. その他の薬物動態試験

本ワクチンのその他の薬物動態試験は実施していない。

9. 考察および結論

ラット PK 試験において，血漿および肝臓中 ALC-0315 濃度は，投与後 2 週間までに最高濃度のそれぞれ約 7000 分の 1 および約 4 分の 1 に減少し，ALC-0159 濃度はそれぞれ約 8000 分の 1 および約 250 分の 1 に減少した。t½は血漿中および肝臓中で同程度で，ALC-0315 は 6～8 日，ALC-0159 は 2～3 日であった。血漿中 t½値は，それぞれの脂質が LNP として組織中に分布し，その後，消失過程で血漿中に再分布したことを表すと考えられる。

ALC-0315 の未変化体は尿中と糞中のいずれにもほとんど検出されなかったが，ラット PK 試験で採取した糞および血漿試料からモノエステル代謝物，二重脱エステル化代謝物および 6-ヘキシルデカン酸が，尿からは二重脱エステル化代謝物のグルクロン酸抱合体が検出された。この代謝過程が ALC-0315 の主要消失機序と考えられるが，この仮説を検証する定量データは得られていない。一方，ALC-0159 は投与量の約 50%が未変化体として糞中に排泄された。In vitro 代謝実験において，アミド結合の加水分解により緩徐に代謝された。

BNT162b2 がコードする抗原の生体内発現分布は LNP 分布に依存すると考えられることから，BALB/c マウスにルシフェラーゼ RNA 封入 LNP を筋肉内投与し，代替レポータータンパク質の生体内分布を検討した。その結果，ルシフェラーゼの発現が投与部位においてみられ，それより発現量は低値であったものの肝臓でも認められた。ルシフェラーゼの投与部位での発現は投与後 6 時間から認められ，投与後 9 日には消失した。肝臓での発現は投与後 6 時間から認められ，投与後 48 時間までに消失した。肝臓への分布は局所投与したルシフェラーゼ RNA 封入 LNP が循環血中に到達し，肝臓で取り込まれたことを示すものと考えられた。また，ラットにルシフェラーゼ RNA 封入 LNP の放射能標識体を筋肉内投与したところ，放射能濃度は投与部位で最も高値を示した。投与部位以外では，肝臓で最も高く，次いで脾臓，副腎および卵巣でも検出されたが，これらの組織における投与量に対する総放射能回収率は肝臓より著しく低かった。この結果は，マウス生体内分布試験において肝臓でルシフェラーゼ発現がみられたことと符合した。なお，ラット反復投与毒性試験で肝障害を示す毒性所見は認められなかった（M2.6.6.3 項）。

以上の非臨床薬物動態評価より，循環血中に到達した LNP は肝臓に分布することが示された。また，ALC-0315 および ALC-0159 の消失には，それぞれ代謝および糞中排泄が関与することが示唆された。

2.6.5.5B. PHARMACOKINETICS: ORGAN DISTRIBUTION CONTINUED

Test Article: [^{3}H]-Labelled LNP-mRNA formulation containing ALC-0315 and ALC-0159
Report Number: 185350

Species (Strain):	Rat (Wistar Han)
Sex/Number of Animals:	Male and female/3 animals/sex/timepoint (21 animals/sex total for the 50 µg dose)
Feeding Condition:	Fed ad libitum
Method of Administration:	Intramuscular injection
Dose:	50 µg [^{3}H]-08-A01-C0 (lot # NC-0552-1)
Number of Doses:	1
Detection:	Radioactivity quantitation using liquid scintillation counting
Sampling Time (hour):	0.25, 1, 2, 4, 8, 24, and 48 hours post-injection

Sample	Mean total lipid concentration (µg lipid equivalent/g (or mL) (males and females combined)							% of administered dose (males and females combined)

Check out the latest tweet from today - The WHO updated their advice....but Scott Weese twisted it

"WHO's Strategic Advisory Group of Experts (SAGE) has concluded that the Pfizer/BionTech vaccine is suitable for use by people aged 12 years and above. Children aged between 12 and 15 who are at high risk may be offered this vaccine alongside other priority groups for vaccination."

The vaccine rollout is spreading - and so is the delta variant. Lots of folks are concerned about the risk of myocarditis in young people who receive mRNA. My advice: make sure your sources include true experts - in this case, doctors who look after heart disease in kids. 1/n

37 128 651

WanderingGirl10 @WanderingGirl10 · Jun 14

My parents need to learn this - last I checked, they were using advice from a VETERINARIAN to argue against getting the mRNA vaccines. 🤦

We need to continue to challenge misinformation.

Unnecessary deaths are going to occur because of these irresponsible people. The number of people that have mentioned they cancelled or are rethinking vax is scary.

We need everyone on board with vax bc of delta.

It seems like Bridle (surprise, surprise) misinterpreted a comment and (surprise, surprise) continues to spew misinformation about it.

I've seen nothing supporting it and how would the person he's accusing have access to Bridle's parents' info?

Just more misdirection.

1

Patti @boobooboobunster · 12h

I see your a collegue of Dr. Bridles. Are you in on the smear? And if so why? Is he not a credible scientist? And if not why are you all just coming forward now?

Subject: Re: Facebook censors Byram's interview

Hi Jeff and thanks for your quick response. As professors and scientists we are used to normal scientific debate, but in this case people are not allowing that process to take place. Instead they post websites using his name, send nasty tweets and Facebook

Posts, and now launch a false fact checker post. I have checked the two critical documents in question myself (attached again here), and indeed these reports state what Byram said (mRNA in LNPs at off target locations and spike protein in circulation following immunization).

These slanderous posts essentially state these documents don't exist or are in some way false. They make extremely negative comments about Byram for even mentioning these two documents. This is not how science works. This is something else entirely. This is social media lashing out at opinions they don't appreciate for unknown reasons.

In my 30 years as a faculty member, I have never seen anything like it. I am grateful that you and the UoG are supporting Byram's right to hold any professional position, which in this case was simply to bring these 2 new pieces of information to light last week at a critical time when parents were trying to make the best decisions around vaccination of their children.

By the way, I just finished reading another review paper that sites several other studies that demonstrate that mRNA within LNPs can be delivered to various off target sites. So it is not as if Byram is the only scientist bringing this information forward.

I strongly encourage you and Shayan to at least glance at these documents, if you have not done so already, so you see that this is not false news. Byram has always been a respected and successful member of our faculty, and I am saddened to see people go after him in such a malicious manner on social media including members of our own

faculty. Some have now even removed him from their grant applications. These types of slanderous posts can have a negative impact on his career and should be actively discouraged. As you point out, there is a scientific process to follow and Byram would be happy to discuss these papers with any interested parties. However, he has not been given that opportunity by the people posting against him for no valid reason.

I am sure many of our students are confused and misinformed about all of this. I used to trust fact checkers. I guess that was naive. If you think of anyway we could support Byram further as a college that would be appreciated.

I have already expressed my support to him over the phone. I trust the truth will come out eventually and justice served. I am just saddened by this negative turn of events when everyone is trying their best to help find our way through this pandemic.

Hello Bonnie,

Thanks for your question.

The College cannot place itself in a position to referee every scientific discourse in the media involving one of its faculty members. We do not comment on our faculty members' scientific positions, but we of course stand by their right to hold such positions as embodied in our commitment to freedom of expression. The nature of peer-reviewed science is that evidence is weighed by the scientific community itself, not by institutions.

I have already communicated to Byram extensively on the full range of options and supports available to him from the university and my office if he believes any conversation has, in his opinion, moved beyond normative scientific discourse and into the arena of harassment or a human rights violation.

I hope this is a helpful answer.

Thanks,

Jeff

Subject: Fwd: Facebook censors Byram's interview

Dear Jeff and Shayan - I hope you are both well. I wanted to let you know that I find it very disappointing that after Byram's interview last week the "Fact Checkers" and others on social media etc called this false news when in fact he reported on two important findings: 1 - the Pfizer report to the Japanese government (linked below, see tables on page 6-7) showing that their LNP formulation carrying mRNA is distributed within 15 minutes to most organs and tissues and remains for at least 48 hours. This bio-distribution study was done in rats which is appropriate and another study in primates showed similar results.

In addition, he spoke about an accepted peer reviewed paper by Ogata et al (authors from UoMontreal and Harvard, linked below) that showed the presence of viral spike protein in the circulation of 11 out of 12 health care workers following immunization with the mRNA 1273 vaccine. This substantiates the idea that the mRNA is being translated into spike protein in large enough quantities and finding its way from the local site/draining nodes into the circulation where it can bind to platelets and endothelial cells potentially causing damage.

This is in no way false information. In fact, it is right here in black and white along with a large number of other reports and manuscripts (I attached just a smattering) describing various concerns associated with these nucleic acid vaccines, particularly for use in children.

Why is it all of a sudden a crime or false news when a group of credible scientists offer up their valid concerns to the public, particularly about vaccinating children?

Pfizer's own studies on ~1100 vaccinated and placebo children between the ages of 12-15 years indicates 0.3-0.4% severe reactions. This would translate to about 54,000 kids in Canada. As we all know this age group is at exceedingly low risk of Covid-19. Additionally, it is becoming clear that there are effective treatments for Covid-19 which reduce any risk even further (P Kori et al Therapeutic Advance 2021).

I am wondering if our College will see fit to make some type of counter statement indicating that they do not see this as false claims but a faculty members professional assessment of reports in the literature.

It is inappropriate in my view to let Byram be slandered by all types of false claims and say nothing. I hope you can offer some suggestions to support our colleague.

All the best in these difficult days. Bonnie

On Jul 7, 2021, at 6:50 PM, Jeffrey Wichtel <jwichtel@uoguelph.ca> wrote:

Thanks Bonnie.

I agree that the debate on public health measures to combat COVID-19 has been vigorous and emotionally charged. Sadly, many of our OVC faculty members have been subject to regrettable commentary in the media, social and otherwise, and this has been the case since spring 2020. As an employer we offer the supports we can and of course hold our employees to acceptable standards of professional behaviour when using UofG-sanctioned communication channels with such as email or verbal communication in the workplace, per our established HR policies.

I will repeat my message to you of June 7: the College cannot place itself in a position to referee scientific discourse in the media involving one of its faculty members, and letters of support or detraction for one view or another do not change this. We do not align ourselves with our faculty members' scientific positions, but we of course stand by their right to hold such positions as embodied in our commitment to freedom of

expression. The nature of peer-reviewed science is that evidence is weighed by the scientific community itself, not by institutions. I have already communicated to Byram extensively on the full range of options and supports available to him from the university.

Thanks again for your comments,

Jeff

Subject: Open Letter Against Prof Byram Bridle

Hi All - I am including you on this email since I think you are already aware of the disruptive open letter against Dr Bridle by several of our faculty. As you can imagine I am extremely disappointed to see the open letter in worms and germs (https://www.wormsandgermsblog.com/) against Byram's view of the literature on the topic of SARS-CoV-2 and related vaccines. It seems some people view his thoughts on the evidence as misinformation, but I can assure you that not all academics have the same opinion. In fact, even Dr Robert Malone, one of the original inventors of the mRNA vaccine platform, agrees with Byram's assessment of the literature (see attached letter from Malone), and recommends some cautions around vaccination of children, as does the WHO. Byram's position is not out of line with that of the WHO and for solid reasons based on emerging data in the literature.

I also have been alarmed to see the false websites, build by unknown people, using Byram's name. There are also members of our faculty that spend large junk of their time on social media twitting out insults about Dr Bridle's credentials and opinions. This is unethical in my opinion, particularly when they have not tried to speak to Byram about the literature or the logic that he is using to comes to his conclusions about the potential toxicity of the spike protein and cautions around vaccinating kids. In fact, it is commonly accepted by most people working in the field that the spike protein has toxic potential and contains a toxic-like epitope (see Lagoumintzis et al., Food and Chemical Toxicology 149:112009, 2021). This is not to be misconstrued that every person coming in contact with the SAR-CoV-2 spike protein will feel toxic effects. In fact, there is still a great deal to learn about this virus and the LNP mRNA vaccines. This is part of the rationale used by Dr Bridle to suggest cautions around child vaccination.

Researchers and physicians from around the world have been contacting me with notes and letters of support for Dr Bridle since they are also alarmed about potential impact on academic freedom. On their behalf, I am attaching a selection of these letters here, so you are aware that he has passionate support from many in the scientific community. I have enjoyed reading these letters and found them very informative. I hope you will take time to do the same.

Many more letters and emails are piling in, and I am sure that Dr Bridle's inbox will be full by the time he comes back from holidays.

I am thankful that the UoG supports academic freedom, but it is disheartening when people call solid scientific evidence, although it may go against the current popular narrative, misinformation. That just is not the case. History will eventually bear out the truth.

I would be happy to discuss this further at any time.

All the best. Bonnie

Dr. Bonnie A Mallard (PhD)
Professor of Immuno-Genetics
Department of Pathobiology
University of Guelph
Guelph, Ontario

I totally agree with Niel that this is getting completely out of hand. What a disgrace to our department , college and university.

Scott has been tweeting slanderous comments against Byram for months now and nothing has been done to stop it.

Meanwhile, Byram is the one being accused of harassment. I think the shoe is on the wrong foot here.

In my 30 years as faculty I have never seen such nonsense. To call Byram an anti-Vaxxer is completely ridiculous since his entire career revolves around vaccine production. Showing a picture of a person shovelling manure and implying this is Byram is beyond belief.

Since when do we not accept other faculty with alternative points of view rather than slandering them on social media.

This must stop. Our department and college is becoming a laughing stock. Bonnie

Faculty and staff at the University of Guelph support SARS-CoV-2 vaccine safety

July 6, 2021

We are a science-based faculty and staff at the University of Guelph who support evidence-based decisions and disagree with misinformation being circulated by a member of the faculty at the Ontario Veterinary College.

COVID-19 is an unprecedented pandemic due to a novel coronavirus. Nearly four million people globally have died as a result, and nearly two hundred million have been reported as infected.[1] Many millions more have suffered and continue to suffer from physical and mental illness associated with the pandemic, isolation, poverty, and the long-term effects of the infection.[2]

Vaccines for SARS-CoV-2 were designed, tested and produced at an unprecedented speed and on an extraordinary scale. The ability to quickly develop safe and effective vaccines was made possible through remarkable global co-operation and by concurrently running clinical trials, not by cutting corners. Many countries rapidly authorized vaccines for emergency use. Various types of vaccines are available, including those based on mRNA coding for the viral spike (S) protein, vector-based DNA vaccines coding for the S protein, and recombinant S protein particles. Two doses of the vaccines (type-dependent) have dramatically reduced illness and infections in many parts of the world.[3] The vaccines are highly effective and have very few adverse effects.[4] The coordinated effort of scientists, pharmaceutical companies, public health and regulatory agencies to produce effective vaccines against COVID-19 for billions of people in less than a year is an achievement previously unimaginable.

Dr. Byram Bridle has stated on multiple platforms and numerous outlets that COVID-19 vaccines are unsafe. These statements are contrary to overwhelming scientific evidence. The S protein generated by or incorporated into vaccines is an effective immunogen but does not alter DNA, does not induce infertility or pass through breast milk, and is not a toxin.[5, 6] Adverse vaccine effects do occur but at a similar or lower frequency than for routine vaccines.[4] In the face of this terrible pandemic, widespread vaccination is the best way out of the devastation we currently face. Many people have limited understanding of the complexities of immunization against infectious agents, and rely on scientists in epidemiology and immunology to share their knowledge and experience, especially at times such as these when fear is high. Misinformation spread by individuals such as Dr. Bridle targets uncertainty.

The University of Guelph, including us, supports freedom of expression. However, as scientists and academics we also have a responsibility to counter misinformation, particularly when the misinformation causes harm. A high rate of vaccine acceptance is essential for prevention of SARS-CoV-2 disease and deaths, and for a return to normalcy. In particular, given the high transmissibility of recent variants, very high vaccination rates among people eligible for vaccination are critical. We are very concerned that people who are not seeking vaccination because of misinformation will suffer ill effects from SARS-CoV-2 infection, will infect others, and will slow the return to a more normal life. Academic freedom is important but should not be a license to spread misinformation that has been clearly refuted, including by authors of publications that Dr. Bridle cites in support of his statements.[7] Some may even consider the University of Guelph complicit by failing to provide a clear and effective response to this misinformation

campaign, which is impacting the reputation of the institution and its faculty. Considering the harmful effects of COVID-19 on individuals and communities, the continued spread of misinformation undermines Canadian public health measures, including our vaccine program, and threatens global health security more broadly.

Therefore, we wish to state publicly that as scientists, faculty, and/or staff of the University of Guelph we stand firmly against the continued spread of factually incorrect and misleading information that is being disseminated by Dr. Bridle. We have confidence that the SARS-CoV-2 vaccines approved for use in Canada are safe and effective, and we wish to reassure the public that as members of the University of Guelph community we fully support evidence-based public health, which includes vaccination against COVID-19.

This is Exhibit "L" to the Affidavit of

Bonnie Mallard, sworn before me on

this 15th day of December 2023

A Commissioner for Taking Affidavits

Amina Sherazee Barrister and Solicitor

JULY 2021

To whom it may concern,

We offer this letter in support of Professor Bridle's exemplary character and scientific intellect, and, most importantly, his right to express his scientific opinions freely and unfettered. We believe the opinions he has expressed regarding SARS-CoV-2 and the new mRNA/DNA vaccinations have always been underpinned and substantiated by the published literature and deductive reasoning. Although his opinions might appear to be contrary to the prevailing narrative, we state emphatically that this is even more reason for him to be permitted to express his thoughts freely and without fear of official censure and abuse.

The very essence of scientific inquiry is based on the principle of constant interrogative thinking and a healthy degree of skepticism and debate in relation to any one biological phenomenon (which applies to other areas of research as well). However, it is with great alarm and deep concern for the principles of the scientific method that we have seen Professor Bridle's very character impugned as he dared to rely on the accumulative scientific data to support his call for the application of caution in relation to the current nucleic acid-based therapy-based vaccinations for COVID-19. In fact, we are disturbed to see the depths to which those who do not agree with him have sunk, including some of his local colleagues. The critical letters, false websites, tweets and posts being sent to attack his character and qualifications are at best sophomoric, and at worse childish, if not criminal. Is it no longer possible to have scientific disagreements without resorting to character assassination? If this is the case, then the pursuit and application of science is in possible jeopardy. The public, which provides the main source of research funding through various government agencies, will no longer be able to trust that unbiased and open scientific debate surrounding new technologies or data still occurs. If we are fortunate, perhaps science is only in a holding pattern and we can still rescue this noble discipline. However, this will occur only if the scientific community is willing to have open conversations about the facts from all viewpoints without resorting to ad hominem attacks or other forms of unfair and wholly inappropriate acts of overt and often times publicly aired vengeance! A return to 'sober scientific thought and argumentation', is the only way we will be able to rebuild trust among the public.

The COVID-19 pandemic has brought a high degree of uncertainty, along with novel technologies that have not been tested widely in humans until now. We recognize and appreciate that these vaccines were developed with the best of intentions, but when serious signals of injury are being observed (as is the case now, Figure 1), the prudent and wise decision is to pause vaccination programs. This is particularly so with the young who are actually at low risk of serious illness with COVID-19, but are currently developing myocarditis following vaccination at an alarming rate! Unfortunately, those that develop myocarditis do not fully 'recover' and are at increased long term risk for an array of cardiological problems ranging from arrhythmias to cardiomyopathy! This alone can be taken as a sign that issues pertaining to the new vaccines must be elucidated, and the science behind the vaccines must be open to scrutiny and debate.

Yet it has been difficult to challenge some of the new ideas due to the sense of urgency. However, it is exactly at times like his that it is critical for all voices to be heard so that regrettable errors can be detected early to prevent serious clinical roblems that might arise in people who have been vaccinated. We see Professor Bridle as one of those expert voices ncouraging people to think carefully about all the evidence and being willing to change direction as warranted when new ata comes to light. Yet, despite the scientific validity of his concerns (echoed recently by a Senior Editor of the British Medical Journal - Peter Doshi, one of the original inventors of nucleic acid vaccine platforms – Dr. Robert Malone, the WHO, and countless others), his messaging and his professional character are being attacked. We do not object to those who argue with his conclusions as this is the very ethos of scientific inquiry. However, we cannot support those who attack is credentials and character or try to remove his presentations from public view.

y its very nature, drug development, and the science associated with this endeavor require that as new data emerge, new inking, possibly even changing of the course of investigation are critically important. In fact, we applaud Professor ridle's courage to bring a debate forward despite knowing that his message might (and evidently has) result(ed) in harsh

confrontation. Professor Bridle has a proven track record in viral immunology, the two key disciplines most closely aligned with understanding and responding to the SARS-CoV-2 viral pandemic. Professor Bridle's expertise has been recognized nationally and internationally. For example, Professor Bridle was the recipient of the 2020 Zoetis Award for Research Excellence at the University of Guelph. He has also made important and novel contributions to the field of cancer research and vaccinology, especially in the development of novel biotherapies. With this in-depth knowledge and experience in hand, he is well-equipped, perhaps better than most that have argued against him, to discuss the virus and the technologies currently employed for its control.

Although the type of criticism Professor Bridle is receiving is not unexpected, it is grossly unethical to take this opportunity to defame his character or to demand the removal of his funding from agencies by which he has been respected and closely aligned for years. This is in fact contemptible. As fellow scientists, we are appalled to see emails to funding agencies demanding the removal of Dr. Bridle's funding. Where would we be without courageous researchers willing to stand up for their ideas and debate the science openly? Many key discoveries would have been lost if others were not willing to listen and exchange ideas.

It has been deplorable to see colleagues berating Professor Bridle on Twitter and Facebook without so much as contacting him to ask for a discussion of the issues. In fact, not one colleague who signed the recent open letter in the "Worms and Germs" blog (www.wormsandgermsblog.com) has taken the time to contact Professor Bridle to discuss his thinking around the literature that he cites. The core academic group, and many others of us signing this petition have taken the opportunity to personally discuss these ideas with Professor Bridle on numerous occasions. Although we may not always endorse every idea he has put forward, we agree totally with a need for caution around the vaccination of children under 18 years of age, particularly without parental consent. We also fully support his right to freedom of speech and academic freedom so that he can express as freely as possible his scientific ideas, which are motivated by his desire to serve and protect the Canadian public.

We also point out that it seems pusillanimous that many of the complaints against Professor Bridle have come from anonymous 'keyboard warriors'. Those who do not provide their identities and are not willing to engage in a fair and open debate of these ideas in front of the public have no business to deride Professor Bridle, although they too have the freedom to be critical of his opinions, even if they (the detractors) are right or wrong. If they are confident that Professor Bridle and others are incorrect, why are his critics unwilling to participate in an open conversation or even a debate? Along these lines, Professor Bridle and many other colleagues requested that the Premier of Ontario, Doug Ford, and any members of the Ontario COVID Task Force participate in an open forum. This invitation was not acknowledged except by local MPs, and no invitation accepted. Invitations to specific colleagues posting negative comments on social media, including those that initiated the open letter in Worms and Germs, have also not been accepted. We believe, given the critical nature of this matter, the issues surrounding COVID vaccinations should be debated in front of the Canadian public by people with differing views. We are confident in the ability of Canadians to draw their own well-thought out conclusions, provided that they are given the opportunity to listen to and think about all sides of the argument whether or not they agree with Professor Bridle.

We were also shocked that individuals, also unknown, have made websites using his name (e.g. https://byrambridle.com/) to post harmful and slanderous comments about Professor Bridle. This site is replete with disinformation and outright lies, which are being promulgated to defame Professor Bridle. Then there are the 'fact checkers'! What, exactly are their credentials? Who are they? And when one reads their so-called fact-checks, it becomes painfully obvious that apart from attacking Professor Bridle or simply being dismissive of his comments, these ghost-like 'experts' cannot challenge Professor Bridle on any grounds that have any scientific merit.

With respect to his position regarding the spike protein being a concern given its vaccine-induced expression in various tissues, including immune privileged sites, there are now many publications demonstrating precisely that the spike protein can be hazardous. We have provided limited reference here, since we are addressing the bigger issues of academic freedom, but will provide more upon request. However, a few key publications are worth mentioning since the idea of the SARS-CoV-2 spike protein being pathogenic seems to be what is most troubling to Professor Bridle's detractors.

(VIRAL IMMUNOLOGIST -UNIVERSITY OF GUELPH, GUELPH, ONTARIO, CANADA)"

A recent paper by Ogata *et al.* (2021) published in Clinical Infectious Diseases (https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciab465/6279075) showed that plasma collected from 11 of 13 health care workers had detectable levels of spike protein and/or S1 antigens as early as one day and up to 28 days (in one individual) following vaccination with the mRNA-1273 Moderna vaccine. Although the amounts of spike proteins were low, it is worthy of further investigation for a number of reasons:

1. Reports of vaccine adverse events such as vaccine-induced thrombocytopenia (VITT) and myocarditis, associated with both the mRNA and DNA vaccines, seem to be due, at least in part, to binding of spike protein to the ACE2 receptor on endothelial cells within the blood vessels. VITT was a key reason why the AstraZeneca vaccine was eventually suspended in Canada and elsewhere.
2. The Pfizer biodistribution data sent to the Japanese regulatory authorities demonstrating in rodents that within 15 minutes of immunization the lipid nanoparticles (LNPs) carrying a mRNA construct could be found in multiple organs and tissues including the blood, bone marrow, brain, ovaries, liver, spleen, adrenal glands and other sites (https://www.naturalnews.com/files/Pfizer-bio-distribution-confidential-document-translated-to-english.pdf). This was of concern, since following traditional vaccination the foreign protein would be expected to stay close to the site of injection and the draining lymph-nodes, but not migrate to various tissues, particularly immune-privileged sites where expression of foreign protein can induce inflammatory damage. These results should at least be confirmed in other species before further vaccination of children. Also, traditional vaccines deliver a known amount of foreign protein, whereas the mRNA and DNA vaccines rely on the host to produce an unknown amount of foreign spike protein. Children may be different than adults with respect to the amount of spike protein they produce due to effects of age and metabolism.
3. The publication by Zhang and Shyy *et al.* (2021) in Circulation Research (https://www.ahajournals.org/doi/full/10.1161/CIRCRESAHA.121.318902) showing that the viral spike protein plays a key role in the disease itself, by allowing attack of the vascular system at the cellular level. This again pointed to a potential concern about any amount of spike protein induction in the circulation.
4. A publication (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7758180/) by Nuovo *et al.* (2021) in the Annals of Diagnostic Pathology showing endothelial cell damage, including within the microvessels of the brain, could readily be induced by viral S1 subunit injection in mice.
5. A recent preprint (https://www.biorxiv.org/content/10.1101/2021.06.25.449905v1) by Patterson *et al.* (2021) showing that human non-classical monocytes capable of causing inflammation, and found in circulation, can carry SARS-CoV-2 S1 protein up to 15 months following infection. In a recent online interview with Dr. Bruce Patterson, he stated that similar observations have been seen post-vaccination. He noted spike proteins carried for many months in monocytic cells associated with long-term effects of COVID-19, and possibly long-term adverse vaccines effects. This requires further investigation.
6. A couple of small studies, one by *Low et al.* (2021) indicated that following BNT162b2 vaccination, there is at least a minimal transfer of vaccine mRNA secretion into human milk (up to 2 ng/ml) (https://doi.org/10.1101/2021.04.27.21256151) and another study by Bertrant *et al.* (2021) documented that a few infants experienced some adverse symptoms, although mild, following suckling from vaccinated mothers. These are small studies imply that vaccine mRNA can be transferred from mothers to infants in breast milk and may cause some symptoms in the children. https://doi.org/10.1101/2021.04.21.21255841).
7. A publication (https://pubmed.ncbi.nlm.nih.gov/33503469/) by Lagoumintzis *et al.* (2021) indicating a small "toxin-like" epitope on the viral spike glycoprotein with homology to a snake venom toxin also requires further investigation.

Many of the troubling features of the SARS-CoV-2 spike protein occur following natural infection, but the difference is that using LNPs has the potential to quickly deliver the mRNA encoding spike to almost all tissues examined. The current mRNA and DNA vaccine platforms are also designed to induce high expression of stable spike on the cell surface, and an inflammatory response is directed against the transfected cells rather than just the virus. Moreover, it seems that whenever the viral spike protein gets into circulation, there is the potential for additional adverse reactions. Even with rare adverse events, this is a large number of people to consider with mass vaccination. We could provide many more publications for discussion, but the aforementioned should be sufficient evidence to help people understand why Professor Bridle suggested

pausing the mass vaccination of children. This recommendation is also in line with a recent WHO cautionary note around the vaccination of children which states "there is not yet enough evidence on the use of vaccines against COVID-19 in children to make recommendation for children to be vaccinated against COVID-19".

These concerning and emerging findings regarding the viral spike protein were unanticipated by all of us, including Dr. Bridle, who admits this openly. However, when Professor Bridle became aware of research showing that the spike protein could be toxic, he concluded that suspending the roll out of these vaccines for children, particularly without parental consent, would be the prudent course of action. Therefore, it is our opinion that Professor Bridle, as an ethical scientist, had no choice but to speak out. His views have not been challenged on a scientific level, and he continues to be open to conversation around these issues. In fact, many world experts agree with his concerns. He participated in international symposia when invited (e.g. COVID Plan B 2020 and 2021, and was hosted by respected colleagues in New Zealand, https://www.covidplanb.co.nz/). He also gave several very informative interviews to the media. The fact that some of these presentations or interviews caused discomfort and debate is not a crime, but is rather a breath of fresh air in what has become a highly censored environment. This environment is tantamount to an echo chamber where those who do not conform are shamed and ridiculed. This is completely anathema to scientific discourse, and is also antithetical to the principles of free speech that are linked inextricably to the maintenance, and improvement of a free and open society.

We also note people's concerns about the variants of concern, including the Delta variant, which is still relatively minor in Canada, but now the most prevalent SARS-CoV-2 strain in England. The current data indicates that although the Delta variant is more transmissible, it is not more virulent. Figure 2 shows that hospitalization rates in England remained low even as the Delta variant became the dominant strain. There is no need for causing further alarm to the public, but rather simply report the facts. Figure 3 indicates death rates in Canada by province also continue to decline. Interestingly, although the overall death rate remains low, the Delta variant appears to be causing more deaths in the vaccinated than the non-vaccinated. The reasons for this are currently being considered, but firm conclusions have not yet been drawn. However, it is well known that the current vaccines do not prevent transmission in a significant portion of vaccinated people.

Another reason for the currently low death and hospitalization rates could be the approach of herd immunity. In fact, several papers point to solid immunity following recovery from COVID-19 (reviewed in https://www.cell.com/cell/pdf/S0092-8674). One publication by a Canadian group reported that >90% of people in the Vancouver area already possessed antibodies to the spike, nucleocapsid and other viral peptides of the SARS-CoV-2 virus (https://insight.jci.org/articles/view/146316). Antibodies are a good indicator of immunity to this virus. Although not every person will produce antibodies following COVID-19, the vast majority will, and since very few people are re-infected one can safely assume that memory cells are also generated. The sophisticated SARS-CoV-2 antibody mapping array described in the paper by Majdoubi *et al.* (2021) was developed in Canada and is an excellent tool that can be used to determine the current level of population immunity in Canada. Immunity from natural exposure to this virus is likely to provide a more broad-based level of protection than vaccine-induce immunity, since the immune system gets to recognize all parts of the virus as opposed to just the spike protein. This could be assessed prior to vaccination, particularly as an alternative vaccinating children until more evidence is available.

Professor Bridle is also well-known for his collaborative research efforts with colleagues at eighteen Canadian institutions. This has best been exemplified by Professor Bridle being a founding member of the highly successful National Centre of Excellence in Biotherapeutics for Cancer Treatment (BioCanRx), as well as being one of fifteen members of the pan-Canadian collaborative research network known as the Canadian Oncolytic Virus Consortium (OVC). These collaborations have led to unique opportunities for highly qualified personnel from OVC to gain interdisciplinary training. Further, these collaborative networks have generated several clinical trials and a spin-off company known as Turnstone Biologics. He has also had notably productive collaborations with scientists such as Dr. Grant McFadden at Arizona State University (a leader in the field of oncolytic virotherapy research) and Dr. Jack Lawler at Harvard University (a leader in the field of cancer vascular normalization research); Professor Bridle has co-authored publications with both. We see no reason for funding agencies to suddenly change their minds about the worth of Professor Bridle's contributions or critical thinking skills. Professor Bridle is making unique and important contributions to his discipline, and we can see no reason that this should not continue well into the future. It would be a great loss for our country to defame one of its own topflight scientists, because he is courageous enough to bring forth a difference of opinion. And to reiterate, his opinions relating to the spike

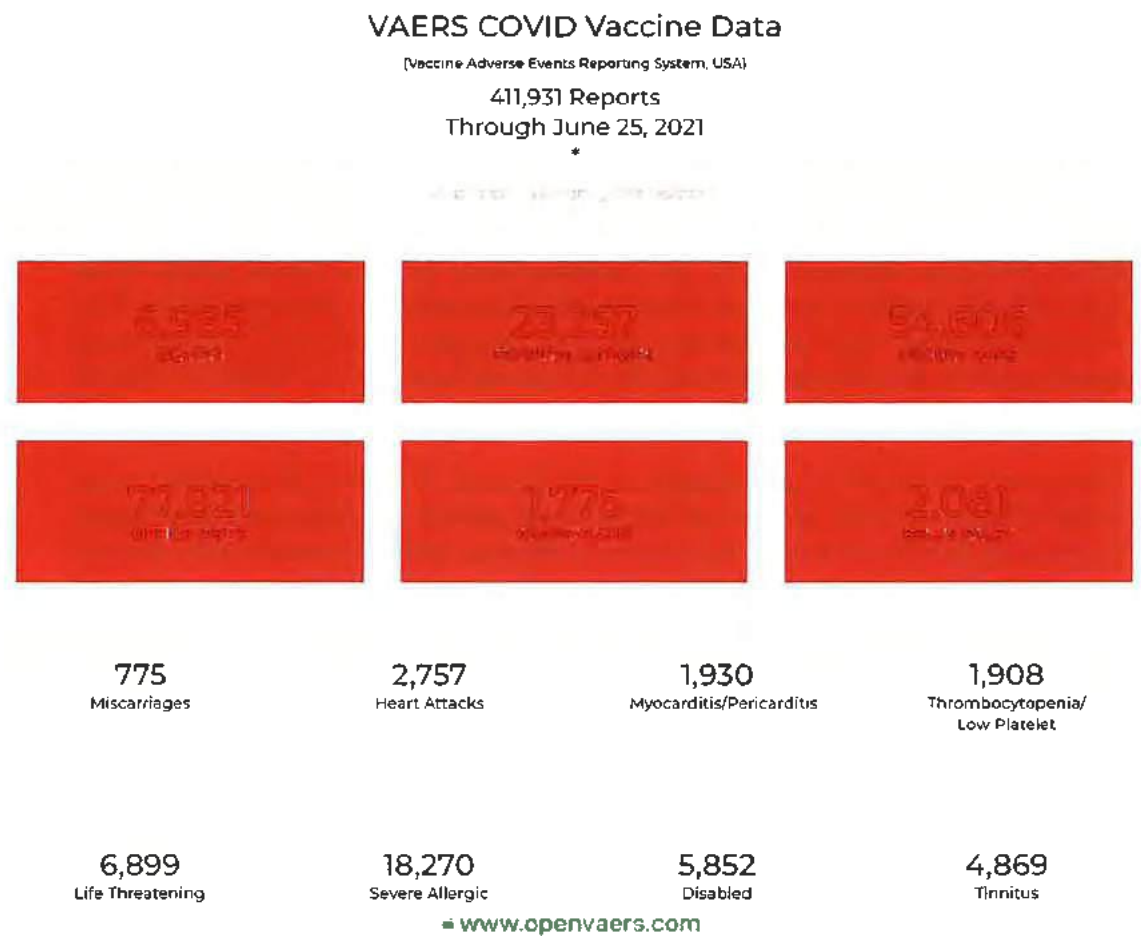
protein, as well as the narrow immunity offered by the mRNA and DNA vaccines are supported by many highly credentialed scientists around the globe, including but not limited to Professor Robert Malone, one of the originators of mRNA technological platforms (https://youtu.be/U1pEtrEr2_s).

Professor Bridle's research over the last several years has been funded by numerous granting agencies including the prestigious Terry Fox Research Institute New Investigator Award, Terry Fox Research Institute Program Project Grant, one Catalyst Grant and one Enabling Grant from BioCanRx, an Innovation Grant that was jointly funded by the Canadian Cancer Society and the CIHR – Institute for Cancer Research (ICR), an Operating Grant that was funded jointly by the Cancer Research Society and the CIHR-ICR), an NSERC Discovery Grant, an operating grant from the Smiling Blue Skies Cancer Fund, and operating grants from the Pet Trust Fund (he was the principal investigator on three and a co-applicant on three). He currently holds government grants to help develop safe and efficacious vaccines against COVID-19. Simply put, he is eminently qualified to speak on this topic.

As colleagues of Professor Bridle, we strongly support his rights to speak as an informed educator and researcher on the topic of COVID-19 vaccination. We fully acknowledge the benefits of vaccination in general, but under the circumstance, support that out of an abundance of caution we should pause mass vaccination of children until we understand the features of the novel nucleic acid vaccines more fully. There are plenty of red flags at the moment and although we are well aware that many governments are moving ahead with mass vaccination of children, we cannot endorse this policy without further investigation.

Figures 1a and b. Number of reported vaccine adverse reactions in US VAERS to June 25, 2021. To date COVID-19-related deaths account for 42% of all vaccine-related deaths in VAERS since it started in 1990 (www.openvaers.com). The reasons for this need to be better understood, but should also be seen as a cautionary sign until further studies are available. It has been estimated that only about 2% of vaccine adverse reactions ever get reported in VAERS.

(VIRAL IMMUNOLOGIST -UNIVERSITY OF GUELPH, GUELPH, ONTARIO, CANADA)"



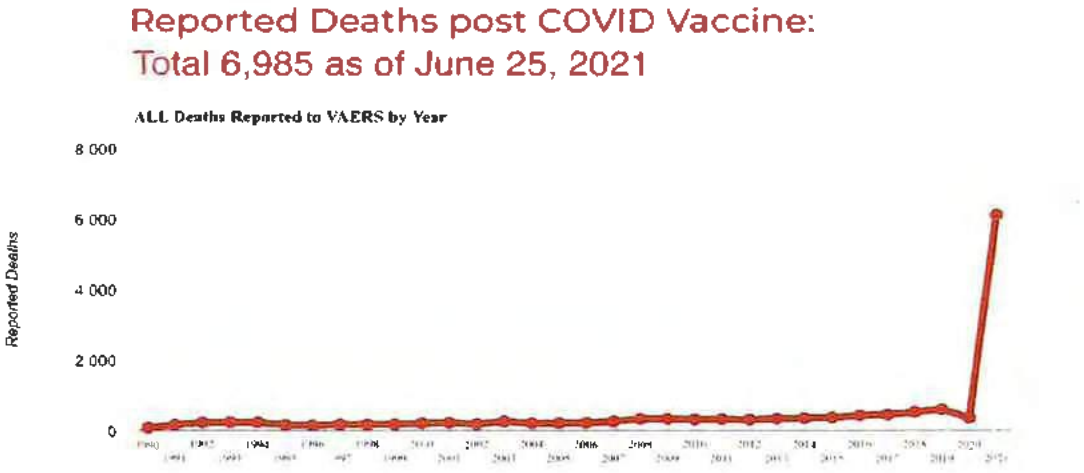


Figure 2. Variant prevalence for all available sequenced cases in England from February 1, 2021 to June 14, 2021 and correlation with hospitalization. Note that the percentage of sequenced SARS-CoV-2 cases corresponding to the Delta variant increased from 5 to 90% from the beginning of April to mid-June (shown in light purple), whereas hospitalization remained low in the same period.

(VIRAL IMMUNOLOGIST -UNIVERSITY OF GUELPH, GUELPH, ONTARIO, CANADA)"

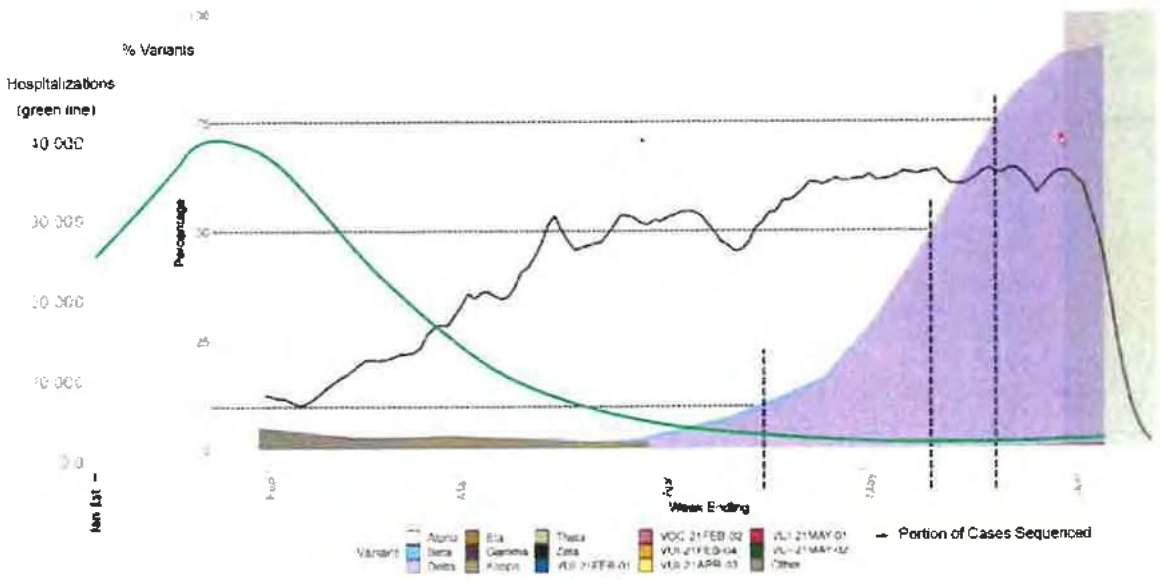

Figure 3. Daily CovidCOVID-19 deaths in Canada by province

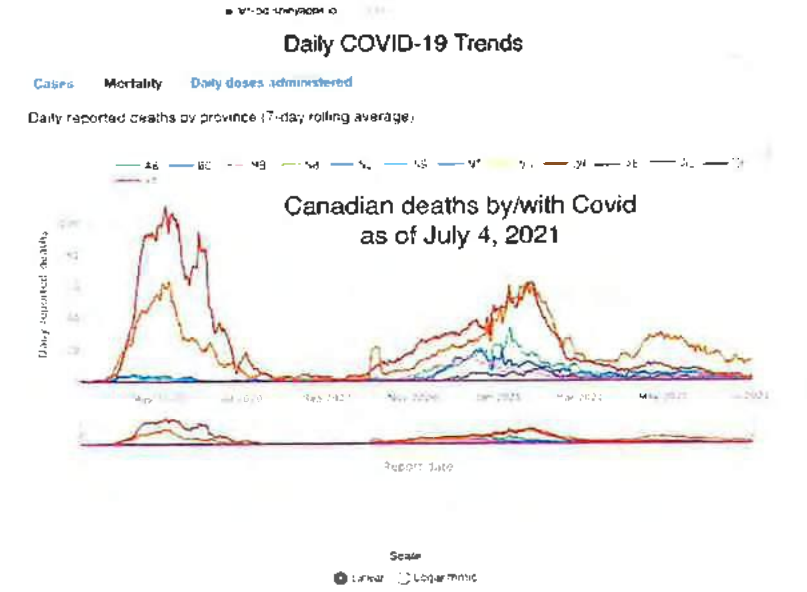

These charts may be viewed on a linear scale (the default) or a logarithmic scale. The choice of scale changes the representation of the plot. Select the scale using the button above. Additionally, the total range of data displayed may be changed using the range slider below the plot. By default, the entire range of data is shown.

Plaintiffs

- and -

UNIVERSITY OF GUELPH, JEFFREY WICHTEL, LAURIE ARNOTT, CHARLOTTE YATES, SCOTT WEESE, GLEN PYLE, ANDREW PEREGRINE, DOROTHEE BIENZLE, AMY GREER, DAVID FISMAN, NICK DULEY, JANE OR JOHN DOE JUNIOR SCIENTIST

Defendants

AFFIDAVIT OF DR. DAVID J. SPEICHER

I, Dr. David J. Speicher, of the City of Hamilton, in the Province of Ontario, MAKE OATH AND SAY:

1. I am a Senior Research Associate at the University of Guelph and an academic and professional colleague of the Plaintiff, and as such, have knowledge of the matters contained in this Affidavit.

Professional, Academic and Research background

2. I am a Canadian molecular virologist with a Bachelor of Science with honours in Biology (major) and Chemistry (minor) from Redeemer University College (Canada). I also have a masters of science with honours in Clinical Microbiology with research focused on the diagnostics and characterisation of human coronaviruses (HCoVs) and a PhD in Virology with research focused on Human Herpesvirus type 8 (HHV-8), both from Griffith University (Australia).
3. Attached and marked as **Exhibit A is a copy of my CV**.

4. I have published just over 30 peer-reviewed scientific manuscripts in the field of infectious diseases.
5. I have obtained just over $1 million in competitive research grants including a $500,000 New Frontiers in Research Fund - Special Call 2022 by Social Sciences and Humanities Research Council (SSHRC), Canada to investigate Canada's response to the COVID-19 pandemic, for work under a project entitled: Project title: Transparency and Shared Responsibility for Sustainable Post-Pandemic Recovery and Evidence-Informed Decision-Making During Future Global Emergencies.
6. I have performed scientific research on a range of infectious diseases including, but not limited to, HCoVs including SARS-CoV-2/COVID, Human Herpesviruses (HHV), Human Papillomavirus (HPV), *Clostridium difficile, Mycoplasma genitalium*, and malaria in Canada, Australia, Kenya, India, and Cambodia.
7. I completed two postdoctoral fellowships at McMaster University/St Joseph's Healthcare Hamilton in Clinical Microbiology and Molecular Epidemiology, and in 2020 received the McMaster University Faculty of Health Sciences Postdoctoral Leadership Award.
8. I was a Sessional Assistant Professor of Biology and Health Sciences (2022-2023) at Redeemer University where I taught courses on Microbiology, Genetics, and Advanced Molecular Methods.
9. I have served as a Senior Research Associate at the University of Guelph under the supervision of Dr. Byram Bridle since September 2021.

Research and Expertise on COVID-19 and COVID-19 vaccines

10. At the start of the pandemic, during my time with McMaster University I designed methods used to sequence SARS-CoV-2[1][2][3].

11. In 2020, I published two manuscripts outlining the federal (Canadian) and provincial (Ontario) response to the COVID-19 pandemic[4][5].

12. I served, from February to April 2021, as the Laboratory Director of Epitome Genomics, which performed up to 10,000 PCR tests per week on asymptomatic people for FH Health.

13. During the pandemic I served, from February to April 2021, as the Laboratory Director of Multiplex Genomics, which performed up to 15,000 PCR tests per week on asymptomatic people for LifeLabs.

14. I have served with Dr. Byram Bridle on the Scientific and Medical Advisory Committee of the Canadian COVID Care Alliance (CCCA) since April 2021. This is a panel of biomedical scientists, medical doctors and other health practitioners that meet weekly on zoom and discuss the science surrounding SARS-CoV-2/COVID-19 including, but not limited to, topics like virology, all cause mortality, COVID vaccines, etc. On this committee Dr. Bridle and I were a part of a team that co-published a critique of the original

6-month clinical study performed by Pfizer/BioNTech on their BNT162b2 RNA vaccine[6]. As part of this committee, I also co-authored a related piece on the manufacturing and quality issues associated with the BNT162b2 mRNA COVID-19 vaccine[7].

15. At the University of Guelph Dr. Bridle and I have co-supervised a PhD candidate, Mr. Jason Knapp, which lead to the co-publishing of a peer-reviewed, review paper[8] and a presentation[9] on oncolytic viral therapy.

16. I was also the lead author and principal investigator on a study that confirmed residual plasmid DNA in both Pfizer and Moderna COVID-19 modified RNA (modRNA) vaccines, and the SV40 enhancer and promoter in the Pfizer COVID-19 vaccine[10].

---

10 Speicher, D.J., Rose, J., Gutschi, L.M., Wiseman, D.M., McKernan, K. (2023) DNA fragments detected in monovalent and Pfizer/BioNTech and Moderna modRNA COVID-19 vaccines from Ontario, Canada: Exploratory dose response relationship with serious adverse events. OSF Preprints. Retrieved from https://osf.io/mjc97/

Dr. Bridle's claims were not and are not "misinformation".

17. When Dr. Bridle did the interview with Alex Pierson, I had only known him for about 1 month.

18. I heard Dr. Bridle's radio interview on Global News Alex Pierson Show on AM640 when it was first aired on May 28, 2021, and again on December 11, 2023, in preparing this affidavit.

19. Dr. Bridle is a viral vaccinologist who is pro-vaccine and pro-evidence-based medical science. Dr. Bridle has very strong moral convictions and is against causing undue harm to any human or animal. Dr. Bridle is a firm advocate of evidence-based science and teaches his students and colleagues to think critically about existing knowledge and the published literature.

20. Dr. Bridle identified the following concerns about the COVID19 vaccines during the interview:

    a. The spike protein is a poor target for COVID vaccines because it's a pathogenic toxic protein.

    b. The COVID vaccine does not stay at the site of injection like first claimed but travels throughout the body.

    c. The spike protein can cross the blood brain barrier and cause harm.

    d. The spike protein can pass in breast milk from a vaccinated mother to a breastfeeding baby.

21. Every single claim made by Dr. Bridle in the interview is correct and accurate. I have re-iterated the facts with the published literature below.

a. Spike protein: There have been many reports that the spike protein is a pathogenic toxic protein that can trigger inflammatory[11,12,13] and neurological conditions[14] without being part of the virus itself.

b. Vaccine Biodistribution: Dr. Bridle's claims about the biodistribution of the COVID-19 vaccine was founded from data in the Japanese study government regulatory study that Dr. Bridle had translated[15]. That same data was submitted and summarized by the European Medicines Agency (see page 47 of the EMA Assessment report for Comirnaty)[16]. This regulatory study is part of the Common Technical Data (CTD), a common set of regulatory documents used by the major regulatory agencies in the western world. The CTD is an internationally agreed format for the preparation of applications regarding new drugs intended to be submitted to regional regulatory authorities in participating countries such as the EMA, SwissMedic, MHRA, HC, FDA and Japan[17].

c. Blood brain barrier: There have been reports that the SARS-CoV-2 spike protein can act like a prion and cross the blood brain barrier[18,19]. Dr. Bridle published a peer-review manuscript showing that the SARS-CoV-2 spike protein can affect the brain and the potential implications of modRNA vaccine spike[20].

d. Breastmilk: The COVID mRNA spike can be transferred to a baby via breast milk following vaccination of a lactating mother[21].

22. This is not the first time Dr. Bridle has accurately predicted problems, stemming from his articulated concerns, surrounding the COVID-19 vaccines, and government measures, such as masking, lockdowns, and PCR testing. Dr. Bridle is a lab-based immunologist and scientist who thinks critically about existing knowledge.

Dr. Fisman's asertions against Dr. Bridle are false

23. Dr. David Fisman has a Doctor of Medicine (MD) and a Master's degree in Public Health (MPH). Dr. Fisman does not hold a PhD and does not specialize in the research and development of vaccines. Dr. Fisman is a tenured professor specializing in epidemiology and the mathematical modeling of infectious diseases.

24. Dr. David Fisman (@DFisman) is someone who I follow on Twitter and am surprised at his continuous discrimination against the unvaccinated. Dr. Fisman continuously uses his Twitter account to communicate these opinions and dislike of "anti-vaxxers". Dr. Fisman's Twitter bio states "Notoriously unfair to … anti-vaxxers". He has often blamed the "anti-vaxxers" for increased viral transmission, and has openly stated that "anti-vaxxers" should

---

[20] Oldfield, P. R., Hibberd, J., & Bridle, B. W. (2021). How Does Severe Acute Respiratory Syndrome-Coronavirus-2 Affect the Brain and Its Implications for the Vaccines Currently in Use. Vaccines (Basel), 10(1). doi:10.3390/vaccines10010001

[21] Fu, W., Sivajohan, B., McClymont, E., Albert, A., Elwood, C., et al. (2022) Systematic review of the safety, immunogenicity, and effectiveness of COVID-19 vaccines in pregnant and lactating individuals and their infants. Int J Gynaecol Obstet. 156(3):406-417. doi:10.1002/ijgo.14008

"stay home" and don't deserve to live in a free society, and that vaccine passports and mandates should be enforced. While he will often refute arguments put forth by those he disagrees with, Dr. Fisman only allows those who @DFisman follows or mentions to reply. Dr. Fisman also referred to "anti-vaxxers" as "cult-like" and that their behaviour "may cause lasting damage to vaccine programs." On October 22, 2021 Dr. Fisman agreed with Geoffrey Johnson that "the anti-vaccine online thugs are increasingly desperate" and that he was going to make "a toast with a glass of anti-vaxxer tears." See **Exhibit B** as a sample of Dr. Fisman's tweets against the unvaccinated.

25. I have read the affidavit of Dr. Fisman filed in the within motion. Dr. Fisman states that Dr Bridle's claims were:
    a. "contrary to overwhelming majority of scientists"; (paragraph 13);
    b. "had potential to harm or halt Ontario's vaccine roll out" (paragraph 15);
    c. "not data-based" (paragraph 19);
    d. "spreading misinformation"; (paragraphs 20, 23, 28, 40);
    e. "not evidence based" (paragraph 25);
    f. "implausible and not data based" (paragraph 30);
    g. "not scientifically sound" (paragraph 41);
    h. "Dr. Bridle's speaking engagements, interviews and articles posed a risk to the public" (paragraph 42);
    i. "Dr. Bridle is suggesting that a study that noted minuscule quantities of spike protein in blood after first dose represent a health hazard. That is poppycock: biologically implausible and not data based." (paragraph 30, Exhibit N, page 184);
    j. "His (Dr. Bridle's) assertions re: accumulation in ovaries is based on an odd document, the original of which is apparently not available, and which looks like it may be a safety study for lipid nanoparticles, not spike as Bridle asserts. This is some kind of drug safety study in rats, not people, and its not possible to assess what was being done here, or even whether it's a real document." (para 30);
    k. "This seems to be an organized disinformation op aimed at undermining vaccine confidence" (para 30);
    l. "…Dr. Bridle…seems to have been headed more and more in the "anti-vax" direction…" (para 30) ;

26. Dr. Fisman has a due diligence as a physician providing expert opinion for public health orders to ensure he is accurate and thorough. Data on biodistribution was available at the time of the Interim Order from Health Canada since they had access to the a Common Technical Document as every regulator. A summary was included in the European Public Assessment Report (EPAR)[22]. Dr. Bridle obtained the full report from Japan. It has since been published by PHMPT (Aaron Siri site) and is now publicly available[23].

27. Dr. Fisman has been pushing the COVID vaccines hard and is discriminatory against the unvaccinated, and Dr. Bridle. Despite several attempts by Dr. Bridle to have a professional scientific discussion with Dr. Fisman, no offer has ever been accepted. In response to Dr. Fisman's allegations I provide the following evidence that Dr. Fisman's claims are false:

    a. With respect to paragraph 13: It was known as early as 2009 that the viral spike protein was toxic[24], and there is no evidence showing that a vaccine version of the spike protein would be any less toxic. The article that Dr. Fisman references a news article that refers to **no** published literature proving that the vaccine spike is different from the virus spike in terms of toxicity. Dr. Fisman, referred to the opinions of "experts" on the field but refers to Dr. Pyle who is not an immunologist let alone an expert on vaccines. However, Dr. Fisman refused to acknowledge that Dr. Bridle as an expert.

---

[22] EMEA/H/C/005735/0000. 2021. Comirnaty European Public Assessment Report (EPAR) [Online]. Available: https://www.ema.europa.eu/en/documents/assessment-report/comirnaty-epar-public-assessment-report_en.pdf.
[23] (2021) SARS-CoV-2 mRNA Vaccine (BNT162, PF-07302048) 2.6.4 薬物動態試験の概要文 (translation: "Summary of pharmacokinetic study")" Retrieved from https://pandemictimeline.com/wp-content/uploads/2021/07/Pfizer-report_Japanese-government.pdf
[24] Dosch, S.F., Mahajan, S.D., Collins, A.R. (2009) SARS coronavirus spike protein-induced innate immune response occurs via activation of the NF-kappaB pathway in human monocyte macrophages in vitro. Virus Res. 142(1-2):19–27. doi:10.1016/j.virusres.2009.01.005

b. With respect to paragraph 15: It puzzles me as to how Dr. Fisman believes that despite the mainstream media and the government pushing for the entire public to get vaccinated that one man, Dr. Bridle, has that much influence to topple the entire vaccine campaign. Informed consent is the cornerstone of medical care yet when Dr. Bridle brings forth the information that he knows Dr Fisman insists on Dr. Bridle being silenced.

c. In several instances (e.g. Paragraphs 19, 20, 23, 28, 40) Dr. Fisman claims that Dr. Bridle's claims are "not data based" and that Dr. Bridle is spreading misinformation. Yet, in all of Dr. Bridle's presentations Dr. Bridle shows a plethora of publications supporting his argument. On the contrary, Dr. Fisman in his affidavit does not produce any scientific evidence for his claim and refers to quotes on social media to support his argument that Dr. Bridle is spreading misinformation rather than openly discuss the scientific literature. Dr. Fisman even admitted that he was unwilling to discuss the science with Dr. Bridle (Paragraph 34).

d. With respect to paragraph 30, Exhibit N, page 184, in regards to Dr. Bridle's claims that miniscule quantities of spike protein in the blood can present a health hazard, note that picogram and fentograms of proteins are toxic, such as botulinum toxin and endotoxin. Therefore the amount of protein available in the blood is not an accurate predictor of its ability to cause harm to human cells.

e. In regards to Dr. Bridle's assertions re: accumulation in ovaries, part of the regulatory submission to which Dr Fisman seems to be unaware which is usually then followed up by subsequent human studies which were not performed.

28. Additionally, each scientific point made by Dr. Bridle during the interview was confirmed by scientists during a panel presentation and discussion at The Future of Medicine: Beyond mRNA vaccines on June 1, 2023 at McGill University (https://www.mcgill.ca/sbms/channels/event/future-medicine-beyond-mrna-vaccines-348383), which I attended live. The replay of that is widely available to the public (https://e1.envoke.com/ext/pages/8168da7a57652e4f6e26474fe17ca814). During this presentation, Anastasia Khvorova (RNA Therapeutics Institute, UMass Chan Medical School) and others admitted that there were issues with the biodistribution (even referred to the Japanese study), and informed consent when rolling out the COVID-19 modRNA vaccines. Prof Mohamad-Gabriel Alameh (Penn Institute for RNA Innovation) stated that the lipid nanoparticles (LNPs) are strong adjuvants, and they need to make them immunologically silent. This is important since the LNPs were assessed by the regulators as novel excipients, which means they are pharmacologically inactive by themselves. This is part of the basis to use the LNPs of the vaccine as platform technology. If classified as an adjuvant, they need different studies for regulatory approval than does excipients. Dr. John Androsavic (Global Head, RNA Medicine Lead, Pfizer) admitted that the "rare" side effects of the vaccine were all due to the spike so don't worry, the next mRNA vaccines will be even safer especially if they can make the LNPs immunologically silent.

29. I have expertise to opine that what was attributed to Dr. Bridle as "misinformation" by Dr. Fisman was in fact scientifically truthful and accurate. The information Dr. Bridle provided did not constitute false or misleading opinions.

False claims of scientists spreading "misinformation" is not in the Public Interest

30. The claims by Dr. Bridle were not "misinformation" but were scientifically sound based on available scientific data. In every instance where Dr. Bridle went public with a statement, he was well researched and presented the facts that he knew. In the scientific method an observation is made, a hypothesis is formulated, tested either empirically in the laboratory or through critically examining the published literature, and then presenting and discussing the findings. Good scientific discussion/debate in the public arena is essential. To stifle scientific discussion or to only listen to one side of the argument is detrimental to the advancement of science and could be harmful to the public, especially during a pandemic. As Premier Doug Ford said, "we need all hands-on deck" and this includes experts in vaccinology like Dr. Byram Bridle.

31. There are several instances during the pandemic where even Health Canada admitted that they made decisions without having all the information. For example, on October 19, 2023 I released a preprint showing excessive residual plasmid DNA in the Pfizer and Moderna COVID-19 modRNA vaccines and an SV40 enhancer-promoter in the Pfizer COVID-19 modRNA vaccines[25]. This work confirmed the initial findings of Kevin McKernan[26] and Dr. Philip Buckhaults[27]. Six hours after the release of my preprint, through an Epoch Times Canada article[28], Health Canada confirmed the presence of DNA

---

[28] https://www.theepochtimes.com/world/exclusive-health-canada-confirms-undisclosed-presence-of-dna-sequence-in-pfizer-shot-5513277

in the Pfizer COVID-19 vaccines that what was previously considered "misinformation" but was in fact accurate.

32. My research study and publication was reported by The Epoch Times on November 7, 2023[29].

33. On October 31, 2023. I was interviewed by Mathew Horwood and Noe Chartier, and on November 27, 2023. I was provided with an email exchange between Mr. Horwood of The Epoch Times and Ms. Ann Madison at Health Canada.

34. Attached and marked as **Exhibit C** is the email exchange between Mr Horwood and Ms. Madison. Additionally on November 28, 2023, I requested access to this information under the *Access to Information Act*, attached as **Exhibit D**. The request is pending.

35. The conclusions I reached as an expert may have been contrary to Public Health or Health Canada information, or "to the overwhelming majority of scientific opinion" but they were accurate. I was also subject to the allegation of "misinformation" by academics commenting outside the ambit of their expertise. Those claims were false.

36. It is therefore not in the public interest to not have scientists and their opinion labelled as "misinformation".

Harms for alleging Dr. Bridle is "an immunologist spreading misinformation"

37. Despite standing on the scientific evidence, people like Dr. Fisman wrongly labelled Dr. Bridle as "spreading misinformation" and "anti-vaxxer" has been detrimental Dr. Bridle's research group, funding, and reputation as a scientist. Prior to the pandemic Dr. Bridle had a growing and very productive research team that was well funded. Since the pandemic

[29] https://www.theepochtimes.com/health/billions-of-copies-of-dna-impurities-and-contaminants-in-a-single-dose-of-covid-19-mrna-vaccine-preprint-5515324?utm_source=partner&utm_campaign=ZeroHedge&src_src=partner&src_cmp=ZeroHedge

and Dr. Bridle's evidence-based scientific stance Dr. Bridle has not been able to obtain new funding. His present research funding is drained, and he is having difficulty getting more research funding to the point where the university is laying off all those employed by Dr. Bridle at the University of Guelph. Even Dr. Bridle's students and colleagues, like me, who have supported him are being unfairly treated due to our association with Dr. Bridle.

38. The damage to Dr. Bridles reputation is not just him but future scientists, such as myself as his former student. I benefited from the depth of his knowledge, the excellence of his teaching methods and the rigor of his research. It is a great loss to the study of research of sciences in Canada as Dr. Bridle is one of the country's leading viral immunologists.

SWORN BEFORE ME by David Speicher in the City of Hamilton, in the Province of Ontario, on this 13th day of December, 2023, in accordance with O. Reg. 431/20 Administering Oath or Declaration Remotely

A Commissioner for Taking Oaths
Rocco Galati B.A. LL.B. LL.M

Dr. David Speicher

This is Exhibit "A" to the Affidavit of
Dr. David Speicher, sworn before me on
this 13th day of December 2023

A Commissioner for Taking Affidavits
Rocco Galati, , B.A., LL.B., LL.M.

CURRICULUM VITAE

David J. Speicher, PhD DTM
Visiting Professor of Biology and Health Sciences
h-index = 14 (Google Scholar)

Business Address
Redeemer University
777 Garner Rd E
Ancaster ON L9K 1J4
P| +1-905-648-2131 x4261 (Ontario, Canada)

Educational Background

2018 – 2020
Post-doctoral Fellow (Bioinformatics and Molecular Epidemiology)
McMaster University, Department of Biochemistry and Biomedical Sciences
M.G. DeGroote Institute for Infectious Disease Research
Hamilton, Ontario, Canada
"*Clostridioides difficile* strain divergence and transmission in Southern Ontario"
Supervisor: Dr. Andrew G. McArthur

2016 – 2018
Post-doctoral Fellow (Molecular and Clinical Microbiology)
McMaster University, Department of Pathology and Molecular Medicine
M.G. DeGroote Institute for Infectious Disease Research
Hamilton, Ontario, Canada
"Oral diagnostics of viruses" and "*C. difficile* and associated phages"
Supervisor: Dr. Marek Smieja

2007 – 2012
PhD (Virology)
Griffith University, Department of Dentistry and Oral Health
Menzies Health Institute Queensland
Gold Coast Campus, Gold Coast, Queensland, Australia
"Characterization of Human Herpesvirus 8 in Australia and Kenya"
Supervisor: Professor Newell W. Johnson CMG

2005 – 2006
MSc with Honours (Clinical Microbiology)
Griffith University, School of Biomolecular and Biomedical Sciences
Sir Albert Sakzewski Virus Research Centre (Royal Children's Hospital)
Brisbane, Queensland, Australia
Project 1: "Incidence and emergence of respiratory viruses in QLD, Australia."
Project 2: "Expression and purification of Coronavirus nucleocapsid proteins."
Supervisor: Associate Professor Theo Sloots

1999 – 2003
BSc. with Honours (Maj: Biology; Min: Chemistry)
Redeemer University College, Ancaster, Ontario, Canada
Undergraduate Project on *Rhodnius prolixus*
Supervisor: Dr. Gary Chiang

David J. Speicher PhD, DTM dspeicher@redeemer.ca

Certificates

2019	Canada Good Clinical Practice (GCP) Certification, CITI Program, Canada
2018	Distinguished Toastmaster, Toastmasters International
2018	Teaching and Learning Scholar, Macpherson Institute, McMaster University, Hamilton, ON, Canada
2018	Foundations of Project Management, Mitacs, McMaster, University, Hamilton, ON, Canada
2017	Teaching and Learning Foundations, Macpherson Institute, McMaster, University, Hamilton, ON, Canada
2014	Advanced Safety in the Field (ASITF), United Nations Department of Safety and Security
2014	Basic Safety in the Field II (BSITF II), United Nations Department of Safety and Security

Honours, Awards, and Scholarships

2022	Local Volunteer of the Year Award, Delta Waterfowl
2022	$5,000. 3rd place, 7th Sunstar World Perio Research Awards. Sunstar Foundation in collaboration with the Journal of Clinical Periodontology, Journal of Dental Research, Journal of Periodontology, Journal of Periodontology Research.
2020	Faculty of Health Sciences Postdoctoral Leadership Award, McMaster, University, Hamilton, ON, Canada
2016	Research Institute Post-Doctoral Fellowship Award, St Joseph's Healthcare Hamilton, Hamilton, ON, Canada
2014	Best Poster, 7th World Workshop on Oral Health & Disease in AIDS. Hyderabad, India. November 6-9, 2014.
2009	Travel Grant, The Mouth and AIDS: The Global Challenge, April 21-24, 2009, Beijing, China
2010 – 2011	Completion Assistance Postgraduate Research Scholarship, Griffith University, QLD, Australia
2008 – 2010	Griffith University Postgraduate Research Scholarship, Griffith University, QLD, Australia
2007 – 2012	Griffith University International Postgraduate Research Scholarship, Griffith University, QLD, Australia
2007	School of Dentistry and Oral Health Postgraduate Research Scholarship, Griffith University, QLD, Australia
2006	Griffith Award for Academic Excellence 2006, Griffith University, QLD, Australia
2005	Griffith Award for Academic Excellence 2005, Griffith University, QLD, Australia

David J. Speicher PhD, DTM dspeicher@redeemer.ca

Professional Organizations

2021 – Present	Scientific and Medical Advisory Committee, Canadian COVID Care Alliance
2007 – Present	American Society for Microbiology
2005 – Present	Toastmasters International
2019 – 2020	Canadian Association of Postdoctoral Scholars
2016 – 2020	Association of Medical Microbiology and Infectious Disease Canada (AMMI)
2006 – 2014	The Australian Society for Microbiology Inc

Employment History

Academic

2021 – Present	Senior Research Associate, University of Guelph, Guelph, ON, Canada
2015 – Present	Honorary Professor, Sree Balaji Dental College& Hospital, Balaji University, Chennai, Tamil Nadu, India
2022 – 2023	Visiting Professor, Redeemer University, Ancaster, ON, Canada
2022 – 2023	Sessional Assistant Professor, Redeemer University, Ancaster, ON, Canada
2022 – 2022	Director of Scientific Operations, Novometrix Research Inc, Guelph, ON, Canada
2021 – 2022	Lab and R&D Director, Multiplex Genomics, Guelph, ON, Canada
2021 – 2021	Laboratory Scientist, Epitome Genetics, Kitchener, ON, Canada
2018 – 2022	Research Associate, St Joseph's Healthcare Hamilton, Hamilton, ON, Canada
2014 – 2022	Senior Research Fellow (Adj), Menzies Health Institute Queensland, Griffith University, QLD, Australia
2014	Senior Research Fellow, Griffith Health Institute, Griffith University, Australia
2011 – 2013	Research Fellow, Griffith Health Institute, Griffith University, QLD, Australia
2001 – 2004	Laboratory Technician, Redeemer University College, Ancaster, ON, Canada

Scholarly & Professional Activities

Executive Positions

2018 – 2020	Co-chair, Executive Committee, Faculty of Health Sciences Postdoctoral Association, McMaster, University, Hamilton, ON, Canada
2016 -- 2018	Inter Campus Liaison Officer, Executive Committee, Faculty of Health Sciences Postdoctoral Association, McMaster, University, Hamilton, ON, Canada

David J. Speicher PhD, DTM dspeicher@redeemer.ca

Professional Development

2021 Project Management for Research and Evaluation, RPM, Toronto, ON, Canada

2021 Grant Writing Webinar Series, American Society of Microbiology

2021 Manuscript Writing and Publishing for Scientists, American Society of Microbiology

2019 23rd Biennial Evergreen International Phage Meeting. Olympia, WA, USA.

2019 High Performance Computing & Machine Learning, SHARCNET and University of Toronto, McMaster, University, Hamilton, ON, Canada

2018 Software/Data Carpentry Workshop, McMaster, University, Hamilton, ON, Canada

2018 'OMICS and Epidemiology workshop, McMaster, University, Hamilton, ON, Canada

2017 12 Irrefutable Laws of Leadership, The John Maxwell Team

2017 Instructional Skills Workshop, Macpherson Institute, McMaster University, Hamilton, ON, Canada

2017 Essentials of Productive Teams, Mitacs, McMaster University, Hamilton, ON, Canada

2016 2nd Global Health Diagnostics Course, McGill Summer Institute in Infectious Diseases and Global Health, McGill University, Montreal, Quebec, Canada

2007 Virology Master Class, June 18-29, 2007, University of Adelaide, South Australia, Australia

Journal Editorships

Teaching and Supervision

Courses Taught

Teaching portfolio available upon request.

Undergraduate

BIO-463/CHE-463	Advanced Techniques in Biochemistry & Molecular Biology (2023), Redeemer University, Canada
BIO-261	Genetics (2023), Redeemer University, Canada
BIO-351	Microbiology (2022), Redeemer University, Canada
2015MSC	Laboratory Instructor (February to April 2007), Griffith University, Australia

Supervisorships

PhD Students (completed)

Surani Fernando — School of Dentistry and Oral Health, Griffith University, QLD, Australia
"Assessing maternal, environmental, and individual risk factors for dental caries in a population of children from Queensland, Australia.
Supervisors: Newell W. Johnson, Paul Scuffham, Rodney Lea, **David J. Speicher**
2015 – 2018

MSc Students (completed)

Bradley McInnes — School of Dentistry and Oral Health, Griffith University, QLD, Australia
"Production of a plasmid construct to produce a new qPCR assay for the detection of Human Herpesvirus 8"
Degree: MSc in Clinical Microbiology
Supervisors: Newell W. Johnson and **David J. Speicher**
July – October 2009

Undergraduate Students (completed)

Victoria Kashchuk — School of Dentistry and Oral Health, Griffith University, QLD, Australia
"Prevalence of HHV-8 in an HIV-negative population in Gold Coast, Australia"
Degree: BDS with Honours
Funding: Colin Cormie Grant via the Australian Dental Research Foundation
Supervisors: Newell W. Johnson and **David J. Speicher**
February 2014 – September 2015

External Examiner - PhD Defense

Laura Gilbert — June 2022 — Memorial University
Recent developments in early detection strategies and population-based screening: the perspectives of cervical cancer and COVID-19

David J. Speicher PhD, DTM dspeicher@redeemer.ca

Guest Lecturing

"Respiratory Viruses and COVID-19" (Nov 14, 2023) in Microbiology (BIO-351), Redeemer University

"Immunology" (June 26, 2019) in Human Physiology (KINE 2P09), Brock University

Research Funding

Principal investigator(s) name underlined on grants listed below. My name is in **bold.**

Project Grants Under Review

None

Project Grants Funded

2022	Funding Agency:	Social Sciences and Humanities Research Council (SSHRC), Canada
	Program Type	New Frontiers in Research Fund - Special Call 2022
	Amount:	$500,000
	Project Title:	Transparency and shared responsibility for sustainable post-pandemic recovery and evidence-informed decision-making during future global emergencies.
	Investigators:	Rinner C, Chaufan C, Chow C, Weirsma E, Rangel J, Wang Y, Aversa J., Francis D, Klakura J, Manwell J, **Speicher D**, Zimmerman J, Valente A, Grandsman A, Welsh D.
2016 (Completed)	Funding Agency:	Australian Dental Research Foundation Inc., Australia
	Amount:	$14,821
	Project Title:	Identifying inherited epigenetic and microbiomic influences of dental caries.
	Investigators:	Fernando S, **Speicher DJ**, Lea RA, Johnson NW
2013 (Completed)	Funding Agency:	Griffith Health Institute, Griffith University, Australia
	Amount:	$15,000
	Project Title:	Maternal, paternal, environmental and genetic influences on dental caries in children.
	Investigators:	Johnson NW, Scuffham PA, Griffiths LR, Fernando S, Lea RA, **Speicher DJ**
2012 (Completed)	Funding Agency:	School of Dentistry and Oral Health, Griffith University, Australia
	Amount:	$5,000
	Project Title:	Detection of Human Immunodeficiency Virus, Human Herpesviruses and Human papillomavirus in Oral Fluids from HIV-positive Patients in Chennai, India.
	Investigators:	**Speicher DJ** and Johnson NW
2012 (Completed)	Funding Agency:	Griffith Health Institute, Griffith University, Australia
	Amount:	$15,000
	Project Title:	Development of a serological algorithm for carriage of, or infection with, HHV-8 for use in Australia, India, and Papua New Guinea.
	Investigators:	**Speicher DJ** and Johnson NW

David J. Speicher PhD, DTM dspeicher@redeemer.ca

Project Grants Funded continued...

2012 (Completed)	Funding Agency:	DNA Genotek Grant Program, Canada
	Amount:	$25,000 plus 400 collection kits.
	Project Title:	Salivary diagnosis of HIV, HHV-8 and HPV in two distinct HIV-positive populations: Port Moresby, Papua New Guinea and Chennai, India.
	Investigators:	**Speicher DJ** and Johnson NW
2011 (Completed)	Funding Agency:	Australian Dental Research Foundation Inc., Australia
	Amount:	$10,271
	Project Title:	Salivary diagnostics of HHV-8 and HPV in Port Moresby, Papua New Guinea: a controlled study of HIV positive and negative subjects.
	Investigators:	**Speicher DJ**, Amarasighe H, Johnson NW
2011 (Completed)	Funding Agency:	Australian Dental Research Foundation Inc., Australia
	Amount:	$5,500
	Project Title:	Saliva as a diagnostic fluid for Human Herpesvirus 8 carriage in man: a controlled study of HIV positive and negative subjects.
	Investigators:	**Speicher DJ**, Johnson NW
2011 (Completed)	Funding Agency:	Griffith Health Institute, Griffith University, Australia
	Amount:	$15,000
	Project Title:	Herpesviruses and human papillomavirus in oral fluids from HIV-positive patients in India.
	Investigators:	Johnson NW and **Speicher DJ**

Equipment Grants

2013	Funding Agency:	Griffith University, Australia
	Amount:	$32,000
	Equipment:	Taylor Wharton Vapour Phase Cryotank
	Investigators:	Hamlet S and **Speicher DJ**
2012	Funding Agency:	Griffith University, Australia
	Amount:	$55,930
	Equipment:	Bio-Rad Gel Doc Ezy, Tecan HydroSpeed Plate Washer, Infors Ecotron with cooling, Memmert Incubator INE550
	Investigators:	**Speicher DJ**
2011	Funding Agency:	Griffith University, Australia
	Amount:	$21,000
	Equipment:	Biometra TProfessional PCR Thermocyclers
	Investigators:	**Speicher DJ**
2010	Funding Agency:	Griffith University, Australia
	Amount:	$190,000
	Equipment:	Eppendorf EpMotion 5075 TMX, Roche LC480 Real-Time PCR machine
	Investigators:	Hamlet S and **Speicher DJ**

Subject: Health Canada - response
To: Matthew Horwood <matthew.horwood@epochtimes.ca>

Good afternoon Matthew,

Please find below the response to your follow up questions. My apologies for the delay in getting back to you.

Thanks and have a good afternoon,
Anna

Can Health Canada confirm that the Pfizer trial used a plasmid-free manufacturing method known as 'Process 1,' and then after the trial scaled up production with plasmids in a manufacturing process known as 'Process 2'?
If that is the case, how can Health Canada be assured the Pfizer vaccines are safe and effective if the trials didn't use plasmid-contaminated vaccines?

Pfizer's "process 1" uses PCR-amplified DNA to produce the COVID-19 vaccine. Although the PCR amplification reaction uses linearized plasmid DNA as template, not intact plasmid, Pfizer "process 1" derived clinical materials are not plasmid-free. The commercial batches of Pfizer's COVID-19 vaccine are produced using "process 2," which only uses linearized plasmid DNA (i.e., no PCR amplification) to produce the vaccine. Both "process 1" and "process 2" include a step to degrade the DNA template into fragments, followed by steps to reduce the quantity of DNA in the final product to below the approved limit. The approved limit for residual DNA is the same for "process 1" and "process 2," and is in line with the recommendation from the World Health Organization. The comparability of the vaccine produced by these two processes was demonstrated based on their biological, chemical and physical characteristics. Therefore, efficacy and safety demonstrated using clinical batches manufactured using "process 1" are also applicable to commercial batches produced using "process 2".

Can you point to the testing data analyzed by Health Canada on the issue? Is it public? Also, are the PCR primers and probes used to make this assessment public?

Testing data analyzed by Health Canada, as well as the PCR primers and probes used, are proprietary information of the vaccine manufacturer. They are not public information. However, the methods used for measuring residual DNA fragments were appropriately validated by the manufacturer and evaluated as fit for purpose by Health Canada. In addition, all Pfizer COVID-19 vaccine commercial batches released in Canada complied with the requirements approved by Health Canada, including the residual DNA.

McKernan asserts that the Pfizer vaccines contain an SV40 Enhancer sequence that is commonly used for gene therapy, but this sequence was not disclosed to the EMA. Do you have information on that matter?

Health Canada cannot comment on information provided to another regulatory authority. Health Canada expects sponsors to identify any biologically functional DNA sequences within a plasmid (such as an SV40 enhancer) at the time of submission. Although the full DNA sequence of the Pfizer plasmid was provided at the time of initial filing, the sponsor did not specifically identify SV40 sequence. When the presence of the SV40 enhancer was raised publicly by McKernan and Buckhaults, it was possible for Health Canada to confirm the presence of the enhancer based on the plasmid DNA sequence submitted by Pfizer against the published SV40 enhancer sequence.

As mentioned in response to the first question, the residual plasmid DNA is present in the final product as DNA fragments, due to the enzyme digestion step in the downstream process. As such, the original risk benefit analysis that supported the initial approval of the Pfizer vaccine continues to be valid.

Finally, information contained here indicates that plasmids are able to enter the nuclei of cells. Is it inaccurate?

https://www.urmc.rochester.edu/labs/dean/projects/nuclear-targeting-of-plasmids-and-protein-dna-comp.aspx

The information on the above website suggests that intact plasmids containing the SV40 enhancer sequence can translocate to the nucleus of cells in culture. However, this information has not been peer reviewed, hence its validity has not been verified. In addition, the DNA plasmid used for the Pfizer vaccine production is linearized, degraded, and reduced in quantity through additional steps. There is no peer reviewed evidence that linearized or fragmented DNA is capable of translocating to the nucleus of cells.

Also this paper discusses genomic integration and seems to contradict your statement about it not being of concern. Is it inaccurate?

https://www.nature.com/articles/s41434-021-00278-2

The paper cited provides evidence that adenovirus vectors have the potential to integrate into genomic DNA. The plasmid used to prepare the Pfizer vaccine does not contain adenovirus virus sequences. Furthermore, as noted in the response to the previous question, there is no evidence that fragmented DNA is capable of translocating to the nucleus of cells.-

AM

Hi Noé and Matthew,

Please find below Health Canada's response to your follow up questions.

Thanks and take care,
Anna

PCR amplification of the plasmid materially alters the nature of the contaminant. PCR often amplifies molecules millions to billions of times. This would make the residual DNA being used for IVT to contain only the Spike sequence and the T7 promoter but eliminate the SV40 sequences and the rest of the 7810 base pair plasmid. While steps are in place to remove these dsDNA's, the documentation given to the EMA shows this step lacks validation and has high variance (815X across 10 vials). Has Health Canada produced any peer reviewed evidence or data regarding your monitoring of this step?

Health Canada cannot comment on information provided by sponsors to other regulatory authorities. The data generated to quantify the residual plasmid DNA was obtained using approved validated methods submitted to Health Canada by the sponsor. These data demonstrated that the residual DNA content in the final product was consistently below the limit approved by Health Canada. The limit for the residual DNA is controlled as not more than 10 ng/human dose, which is in line with the World Health Organization's recommendation concerning residual DNA in biological drugs.

How does Health Canada evaluate if a PCR assay is fit for purpose if the primers are proprietary? If the qPCR primers used to evaluate dsDNA contamination lie outside of the PCR amplification Pfizer is using to amplify their plasmid DNA, then these primers will report a false result. Given the Pfizer sequence is public and often mandated, why are qPCR primers used to evaluate the dsDNA contamination proprietary? Are any CT values for this dsDNA assessment available for public review?

Please note that the manufacturer does provide proprietary information and data to Health Canada for evaluation, which includes the type of methods, or details of the methods, used for manufacturing and control. The proprietary nature of the information indicates that this information is not disclosed publicly.

DNA-based vectors are very analogous to DNA adenovirus vectors. And there is evidence of SV40 virus integrating into genomes: *https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2913896/*. ***There is also ample evidence SV40 plasmids containing the same elements in the vaccines can integrate:*** *https://journals.asm.org/doi/10.1128/JVI.68.2.787-796.1994?url_ver=Z39.88-2003&rfr_id=ori:rid:crossref.org&rfr_dat=cr_pub%20%200pubmed*. ***Has Health Canada performed any work to assess if this genome integration is happening? Can Health Canada or manufacturers prove without the shadow of a doubt it isn't?***

The Pfizer DNA plasmid used to produce the COVID-19 vaccine is distinct from DNA adenovirus vectors in sequence and biological functions. Furthermore, the Pfizer plasmid does not contain sequences corresponding to SV40 proteins studied in the paper cited. Therefore, the integration mechanisms described are not applicable.

Subject: Re: Health Canada - response

Hi Anna,

Thank you very much for the detailed response. My colleague Matthew is on vacation so I will send you what is hopefully one last round of questions. We are grateful for your time and that of the specialists going over this.

Your answer:
Pfizer's "process 1" uses PCR-amplified DNA to produce the COVID-19 vaccine. Although the PCR amplification reaction uses linearized plasmid DNA as template, not intact plasmid, Pfizer "process 1" derived clinical materials are not plasmid-free. The commercial batches of Pfizer's COVID-19 vaccine are produced using "process 2," which only uses linearized plasmid DNA (i.e., no PCR amplification) to produce the vaccine. Both "process 1" and "process 2" include a step to degrade the DNA template into fragments, followed by steps to reduce the quantity of DNA in the final product to below the approved limit. The approved limit for residual DNA is the same for "process 1" and "process 2," and is in line with the recommendation from the World Health Organization. The comparability of the vaccine produced by these two processes was demonstrated based on their biological, chemical and physical characteristics. Therefore, efficacy and safety demonstrated using clinical batches manufactured using "process 1" are also applicable to commercial batches produced using "process 2".

Follow-up question:
PCR amplification of the plasmid materially alters the nature of the contaminant. PCR often amplifies molecules millions to billions of times. This would make the residual DNA being used for IVT to contain only the Spike sequence and the T7 promoter but eliminate the SV40 sequences and the rest of the 7810 base pair plasmid. While steps are in place to remove these dsDNA's, the documentation given to the EMA shows this step lacks validation and has high variance (815X across 10 vials). Has Health Canada produced any peer reviewed evidence or data regarding your monitoring of this step?

Your answer:
Testing data analyzed by Health Canada, as well as the PCR primers and probes used, are proprietary information of the vaccine manufacturer. They are not public information. However, the methods used for measuring residual DNA fragments were appropriately validated by the manufacturer and evaluated as fit for purpose by Health Canada. In addition, all Pfizer COVID-19 vaccine commercial batches released in Canada complied with the requirements approved by Health Canada, including the residual

released in Canada complied with the requirements approved by Health Canada, including the residual DNA.

Follow-up question:
How does Health Canada evaluate if a PCR assay is fit for purpose if the primers are proprietary? If the qPCR primers used to evaluate dsDNA contamination lie outside of the PCR amplification Pfizer is using to amplify their plasmid DNA, then these primers will report a false result. Given the Pfizer sequence is public and often mandated, why are qPCR primers used to evaluate the dsDNA contamination proprietary? Are any CT values for this dsDNA assessment available for public review?

Your answer:
https://www.urmc.rochester.edu/labs/dean/projects/nuclear-targeting-of-plasmids-and-protein-dna-comp.aspx

The information on the above website suggests that intact plasmids containing the SV40 enhancer sequence can translocate to the nucleus of cells in culture. However, this information has not been peer reviewed, hence its validity has not been verified.

In addition, the DNA plasmid used for the Pfizer vaccine production is linearized, degraded, and reduced in quantity through additional steps. There is no peer reviewed evidence that linearized or fragmented DNA is capable of translocating to the nucleus of cells.

Follow-up comment:
The work of David Dean has been peer reviewed and published. The web link was just a general reference.
https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4152905/
https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4150867/
https://www.cell.com/molecular-therapy-family/molecular-therapy/fulltext/S1525-0016(16)30801-2
https://www.jbc.org/article/S0021-9258(20)38527-6/fulltext

Dean demonstrates that the 72bp SV40 enhancer is all that is required to recruit transcription factors that localize DNA to the nucleus.

Your answer:
https://www.nature.com/articles/s41434-021-00278-2

The paper cited provides evidence that adenovirus vectors have the potential to integrate into genomic DNA. The plasmid used to prepare the Pfizer vaccine does not contain adenovirus virus sequences. Furthermore, as noted in the response to the previous question, there is no evidence that fragmented DNA is capable of translocating to the nucleus of cells.-

Follow-up question:
DNA-based vectors are very analogous to DNA adenovirus vectors.

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2913896/

There is also ample evidence SV40 plasmids containing the same elements in the vaccines can integrate:
https://journals.asm.org/doi/10.1128/JVI.68.2.787-796.1994?url_ver=Z39.88-2003&rfr_id=ori:rid:crossref.org&rfr_dat=cr_pub%20%200pubmed

2008&rft_id=info:doi/10.1016/j.vaccine.2008.04.014&rft_dat=<rft_pub%20%20[pubmed

Has Health Canada performed any work to assess if this genome integration is happening? Can Health Canada or manufacturers prove without the shadow of a doubt it isn't?

Thank you and best regards,

Subject: Health Canada - response
To: Matthew Horwood <matthew.horwood@epochtimes.ca>

Good afternoon Matthew,

Please find below the response to your follow up questions. My apologies for the delay in getting back to you.

Thanks and have a good afternoon,
Anna

Can Health Canada confirm that the Pfizer trial used a plasmid-free manufacturing method known as 'Process 1,' and then after the trial scaled up production with plasmids in a manufacturing process known as 'Process 2'?
If that is the case, how can Health Canada be assured the Pfizer vaccines are safe and effective if the trials didn't use plasmid-contaminated vaccines?

Pfizer's "process 1" uses PCR-amplified DNA to produce the COVID-19 vaccine. Although the PCR amplification reaction uses linearized plasmid DNA as template, not intact plasmid. Pfizer "process 1" derived clinical materials are not plasmid free. The

intact plasmid, Pfizer "process 1" derived clinical materials are not plasmid-free. The commercial batches of Pfizer's COVID-19 vaccine are produced using "process 2," which only uses linearized plasmid DNA (i.e., no PCR amplification) to produce the vaccine. Both "process 1" and "process 2" include a step to degrade the DNA template into fragments, followed by steps to reduce the quantity of DNA in the final product to below the approved limit. The approved limit for residual DNA is the same for "process 1" and "process 2," and is in line with the recommendation from the World Health Organization. The comparability of the vaccine produced by these two processes was demonstrated based on their biological, chemical and physical characteristics. Therefore, efficacy and safety demonstrated using clinical batches manufactured using "process 1" are also applicable to commercial batches produced using "process 2".

Can you point to the testing data analyzed by Health Canada on the issue? Is it public? Also, are the PCR primers and probes used to make this assessment public?

Testing data analyzed by Health Canada, as well as the PCR primers and probes used, are proprietary information of the vaccine manufacturer. They are not public information. However, the methods used for measuring residual DNA fragments were appropriately validated by the manufacturer and evaluated as fit for purpose by Health Canada. In addition, all Pfizer COVID-19 vaccine commercial batches released in Canada complied with the requirements approved by Health Canada, including the residual DNA.

McKernan asserts that the Pfizer vaccines contain an SV40 Enhancer sequence that is commonly used for gene therapy, but this sequence was not disclosed to the EMA. Do you have information on that matter?

Health Canada cannot comment on information provided to another regulatory authority. Health Canada expects sponsors to identify any biologically functional DNA sequences within a plasmid (such as an SV40 enhancer) at the time of submission. Although the full DNA sequence of the Pfizer plasmid was provided at the time of initial filing, the sponsor did not specifically identify SV40 sequence. When the presence of the SV40 enhancer was raised publicly by McKernan and Buckhaults, it was possible for Health Canada to confirm the presence of the enhancer based on the plasmid DNA sequence submitted by Pfizer against the published SV40 enhancer sequence.

As mentioned in response to the first question, the residual plasmid DNA is present in the final product as DNA fragments, due to the enzyme digestion step in the downstream process. As such, the original risk benefit analysis that supported the initial approval of the Pfizer vaccine continues to be valid.

Finally, information contained here indicates that plasmids are able to enter the nuclei of cells. Is it inaccurate?
https://www.urmc.rochester.edu/labs/dean/projects/nuclear-targeting-of-plasmids-and-protein-dna-comp.aspx

The information on the above website suggests that intact plasmids containing the SV40 enhancer sequence can translocate to the nucleus of cells in culture. However, this information has not been peer reviewed, hence its validity has not been verified. In addition, the DNA plasmid used for the Pfizer vaccine production is linearized, degraded, and reduced in quantity through additional steps. There is no peer reviewed evidence that linearized or fragmented DNA is capable of translocating to the nucleus of cells.

Also this paper discusses genomic integration and seems to contradict your statement about it not being of concern. Is it inaccurate?
https://www.nature.com/articles/s41434-021-00278-2

The paper cited provides evidence that adenovirus vectors have the potential to integrate into genomic DNA. The plasmid used to prepare the Pfizer vaccine does not contain adenovirus virus sequences. Furthermore, as noted in the response to the previous question, there is no evidence that fragmented DNA is capable of translocating to the nucleus of cells.-

AM

Hi Noé,

Please find below Health Canada's response to your latest follow up questions.

Thank you,
Anna

Have you tried to independently verify other findings made by the scientists? Are you able to disprove Buckhaults' latest assertion, without relying on old assurances given by the manufacturer?

As noted previously, based on our evaluation of the data and scientific information for the vaccine, we have concluded that the risk/benefit profile continues to support the use of the Pfizer-BioNTech vaccine.

Health Canada does not rely on the conclusions provided by vaccine manufacturers. Health Canada conducts an in-depth independent review of the required evidence provided by the manufacturer to ensure that our high standards for safety, efficacy and quality are met. The Department works in close collaboration with international agencies including other regulators and the World Health Organization to ensure that vaccines available are safe and effective.

Are you currently assessing what would be the impact on the health of Canadians if Buckhaults is right about there being a genome modification?

As previously noted, the presence of residual plasmid DNA in the mRNA COVID-19 vaccines does not change Health Canada's assessments of the safety of these vaccines. In addition, scientists have been working to develop plasmid DNA based vaccines against infectious diseases since the 1990s. Although chromosomal integration of the plasmid DNA was initially a major theoretical concern, the data obtained to date do not support this concern.

Furthermore, the plasmid used to prepare the Pfizer-BioNTech vaccine does not contain adenovirus virus sequences, and there is no peer reviewed evidence that linearized or fragmented DNA is capable of translocating to the nucleus of cells.

Subject: Genome modification

Good day,

Scientist Dr. Buckhaults said yesterday "i guarantee you there has been genome modification" in reference to his latest findings surrounding covid vax contamination. https://twitter.com/P_J_Buckhaults/status/1691596093422006333

I know Health Canada's position on the matter, which you relayed to us in recent weeks. But you've also admitted having been unaware of the presence of SV40 in the vax, until McKernan and Buckhaults made the independent finding.

Have you tried to independently verify other findings made by the scientists?

Are you able to disprove Buckhaults' latest assertion, without relying on old assurances given by the manufacturer?

Are you currently assessing what would be the impact on the health of Canadians if Buckhaults is right about there being a genome modification?

Thank you and best regards,

To: matthew.horwood@epochtimes.ca <matthew.horwood@epochtimes.ca>

Hi Matthew,

Thanks for your patience. Please find below Health Canada's response to your enquiry.

Thaks,

Anna

I was wondering if Health Canada/PHAC have checked COVID-19 vaccine vials for plasmid contamination if they are aware of this issue and are tracking it, and what the impacts on health and human DNA could be if the findings of McKernan and Buckhaults are correct.

Plasmids are an essential starting material for the production of mRNA vaccines. During the downstream process in mRNA vaccine manufacturing, the plasmid DNA is digested with enzymes to small fragments, and further removed to a level of not more than 10 ng/human dose, which is in line with the World Health Organization's recommendation concerning residual DNA in biological drugs. The DNA is digested with enzymes post-transcription.

Health Canada was aware of the presence of residual plasmid DNA as a process-related impurity during review and prior to the authorization of the mRNA COVID-19 vaccines. In addition, the release testing data for every COVID-19 vaccine lot released into the Canadian market were reviewed and deemed to meet the requirements approved by Health Canada. Furthermore, different assays assessing the same vaccine property, or even the same assay being performed in different laboratories, may generate different results.

It is important to assess the results using the authorized validated assays performed by the vaccine manufacturers to ensure that the quality of commercial vaccine lots are comparable to lots shown to be safe and efficacious in clinical studies.

We are aware HC has previously stated that the mRNA vaccines are not "gene altering therapies," but would DNA plasmid contamination on that reported scale change that assessment?

The presence of residual plasmid DNA in the mRNA COVID-19 vaccines does not change the safety assessment of these vaccines by Health Canada. In addition, scientists have been working to develop plasmid DNA based vaccines against infectious diseases since the 1990s. Although chromosomal integration of the plasmid DNA was initially a major theoretical concern, the data obtained to date do not support this concern. Additional details concerning the safety of plasmid DNA can be found in the following guidance documents:

- US FDA Guidance for Industry Considerations for Plasmid DNA Vaccines for Infectious Disease Indications
- WHO TRS N°1028, Annex2, Guidelines on the quality, safety and efficacy of plasmid DNA vaccines

Defendants

AFFIDAVIT OF DR. HARVEY RISCH

I, Dr. Harvey Risch, of the Town of Fairfield, in the State of Connecticut, SOLEMNLY AFFIRM AND SAY:

1. I am a Professor Emeritus of Epidemiology at Yale School of Public Health, and as such, have knowledge of the matters contained in this Affidavit.

Professional, Academic and Research background as it relates to COVID 19 public health

2. I have a degree in medicine (MD) from the University of California San Diego and PhD, in mathematical modeling of infectious epidemics, from the University of Chicago. Attached and marked as "**Exhibit A**" is a copy of my CV.
3. In my medical training, a substantial fraction, perhaps 20-25%, was of infectious organisms, infectious diseases and their treatments. My PhD subject area was in mathematical modeling of infectious epidemics, and I published on this early in my academic career. Over the subsequent 40-plus years, as an appreciable part of my scientific research into the causes of various types of cancers, I studied the roles of infectious agents

and of their treatments. I also extensively studied the role of medications usage more generally with respect to cancer causation, and I have created and taught at Yale a graduate course covering pharmacoepidemiology, the epidemiologic study of drugs and their indications for use, to public health graduate students, law students and medical residents.

4. I am an elected member of the Connecticut Academy of Science and Engineering. Early during the Covid-19 pandemic, I was invited to participate in a scientific workshop panel of the Academy to provide advice to the Governor of Connecticut with respect to reopening the state after its lockdown. My role on the panel was to address possible outpatient Covid-19 treatments. From research that I did at that time, I published, on May 27, 2020, a long and detailed analysis of outpatient Covid-19 treatment efficacy and safety (https://academic.oup.com/aje/article/189/11/1218/5847586) that has now been viewed more than 166,000 times and downloaded more than 91,000 times. Subsequently, as further relevant Covid-19 outpatient treatment studies were published, I examined them and updated my summary analyses (https://earlycovidcare.org/wp-content/uploads/2021/09/Evidence-Brief-Risch-v6.pdf).

5. Additionally, I worked with medical and public health colleagues in Brazil to carry out a study of medications for outpatient Covid treatment and risk of hospitalization. This study was published (https://www.sciencedirect.com/science/article/pii/S1477893920304026).

6. I have continued over the course of the Covid-19 pandemic to study various aspects of the virus, vaccines, treatments, prevention, etc. In particular, I have collaborated with Dr. Peter McCullough and other medical researchers in the development and writing of two publications covering the medical management of outpatient Covid-19 illness in the pre-omicron era (https://www.imrpress.com/journal/RCM/21/4/10.31083/j.rcm.2020.04.264

and https://www.amjmed.com/article/S0002-9343(20)30673-2/fulltext), and have published on the evaluation of medical evidence during the Covid pandemic (https://onlinelibrary.wiley.com/doi/10.1111/ajes.12539). I have also written a number of lay essays on medical and scientific topics related to Covid pandemic management and policies. These essays have appeared in various newspapers and on the Brownstone Institute website (for example, https://brownstone.org/articles/covid-19-vaccine-mandates-fail-the-jacobson-test/).

7. More generally, I have been a professor of epidemiology for more than 40 years, first at the University of Toronto and then at Yale. I have been a fellow of the American College of Epidemiology since 1991. I have a research publication h-index of 111 (indicating high productivity and recognition) and have published more than 400 original peer-reviewed scientific research papers in the medical literature; those papers have been cited by other scientific publications more than 51,500 times. I have won honorary prizes for my epidemiologic research (for example, https://columbiasurgery.org/news/ruth-leff-siegel-award and https://aacrjournals.org/pages/h-a-risch-bio). I am an Associate Editor of the *Journal of the National Cancer Institute*, Editor of the *International Journal of Cancer*, and served for a six-year term as a Member of the Board of Editors of the *American Journal of Epidemiology*. Finally, I have taught coursework to MPH and PhD public health students on introductory epidemiologic methods, intermediate epidemiologic methods, and throughout my whole academic career, advanced epidemiologic methods.

Dr. Fisman is not qualified to opine on Dr. Bridle's area of expertise

8. I have read the affidavit of Dr. Fisman, filed in the within motion. I have written extensive observations and points about many of the items discussed by Dr. Fisman, wherein I attach as "**Exhibit B**". These observations and points are under solemn affirmation along with the body of my affidavit. I have also read Dr. Fisman's CMAJ modeling paper (https://www.cmaj.ca/content/194/16/E573) as well as Dr, Bridle's criticism of that paper (https://viralimmunologist.substack.com/p/fiction-disguised-as-science-to-promote). I have downloaded and explored Dr. Fisman's Excel version of his CMAJ publication model.
9. Dr. Fisman is an MD specializing in infectious disease and a professor of epidemiology. I am also an MD and PhD professor (now emeritus) of epidemiology. Dr. Bridle is a PhD associate professor of immunology and vaccinology. Neither I nor Dr. Fisman have the depth of expertise in viral vaccines and viral immunology possessed by Dr. Bridle.
10. Dr. Fisman claims that Dr. Bridle's expert opinions are not "data based". Such a statement is vague and non-scientific and requires specific examples in order to judge its veracity. Furthermore, scientific expertise can be subjective and narrowly tailored to the scientific questions at hand, and can reflect very different scientific worldviews between even closely related disciplines. Thus, what may be appropriate and consistent with scientific understandings and standards in one field may be devalued by scientists in other, even adjacent, fields. Dr. Fisman is not a viral vaccinologist or a viral immunologist and thus is not qualified to criticize Dr. Bridle on specific scientific opinions in those disciplines.

11. Epidemiologists and medical doctors, even those specializing in infectious diseases, do not have the depth of scientific expertise of viral immunologists researching and developing vaccines.

Expression of expert opinion does not undermine public health

12. Dr. Bridle is an expert on vaccines. Raising questions on the development and use of COVID-19 vaccines does not harm public health objectives.

13. Public health objectives must be based on accurate and timely scientific knowledge. Scientific knowledge is based on objective evidence, not on opinions of scientists. Objective scientific evidence is established by experts doing research studies and by asking and answering questions about the evidence, debating the evidence. Evidence must be interpreted, and interpretations can be subjective. Therefore, all evidence is open to discussion and criticism as part of the process by which it becomes scientifically established. Even during a declared public health emergency, the processes of science are not abrogated, and expert discussion and criticism of evidence and of policies derived from such evidence are de rigueur. If such expert open discussion and criticism is blocked or censored, that has the potential to undermine public health because accurate and objective evidence may not be established. This problem is compounded when public health agencies accumulate empirical evidence but do not release this evidence to experts for analysis or discussion.

False allegation of "Misinformation" is contrary to Public Interest

14. I am a professor (emeritus) at Yale University, which along with the University of Chicago (https://freeexpression.uchicago.edu/) and other universities has a long tradition of academic freedom of expression (https://yalecollege.yale.edu/get-know-yale-college/office-dean/reports/report-committee-freedom-expression-yale). Academic freedom means the ability to espouse dissenting scientific ideas publicly, without punishment. The amelioration of wrong scientific ideas occurs by the same academic freedom, to present countering correct scientific ideas, to allow independent and objective review in order to determine which of the ideas are more likely to be correct. Academic freedom certainly includes expert questioning and criticizing of public health and dominant government narratives.

15. Dr. Bridle is a faculty member at the University of Guelph. The University of Guelph has a policy supporting academic freedom of expression (https://www.uoguelph.ca/freedom-of-expression/policy).

16. Dr. Bridle is expert in the areas of vaccine development and vaccine performance, and in the immunology underlying such areas. As such, he is within the category of people appropriate to comment publicly on these topics.

17. The terms "misinformation" and "disinformation" are being misused as purported rationales for censorship of debate and dissenting views. This misuse of these labels creates a climate of intolerance to dissenting views and opinions. Additionally, these terms are irrelevant for public academic expression under legal free speech and university policies of freedom of expression.

18. Misuse of these terms has resulted in the abandonment of the academic and scientific value of debate and intellectual inquiry. This damages what would be the results of such debate and inquiry, the advancement of scientific knowledge, including knowledge about public health and public-health policies. These terms serve to censor academic and public speech, including by experts, without providing evidence of error in such speech. Censorship is not debate. If expert public or academic speech is in error, the counter to it is more speech not censorship. Employing the terms “misinformation” and “disinformation” thus is not in the public interest and harms the public interest.

Scholarly critique of publication is not "retaliatory" ad hominem attack on Dr. Fisman

19. I have read the paper co-authored by Dr. Fisman, Impact of population mixing between vaccinated and unvaccinated subpopulations on infectious disease dynamics: implications for SARS-CoV-2 transmission | CMAJ. I have also read Dr. Bridle's paper titled Fiction Disguised as Science to Promote Hatred- Article by Dr. Byram W. Bridle – Canadian Covid Care Alliance. As an epidemiologist, I can confirm that in his criticism, Dr. Bridle has accurately identified numerous serious flaws in the study by Fisman et al. I have explored the Excel model version made available by Dr. Fisman, and thank him for thinking to make his model generally available so that experts such as Dr. Bridle and I can evaluate its properties and performance. I note that this model is very similar to the epidemic model that I developed in my PhD dissertation (https://www.sciencedirect.com/science/article/abs/pii/0025556483900470).

20. The main problem that Dr. Bridle criticizes in the Fisman et al. paper and model is that the conclusions of the paper are exquisitely sensitive to the numerical values employed in the model, and that some of those numerical values are unrealistic, to the degree that realistic

values would result in conclusions opposite to those stated in the paper. There are a number of these issues here that I will illustrate in the next four paragraphs.

21. First, Dr. Fisman's model assumes parameter values taken from the initial waves of the Covid pandemic, through the delta variant. All of the parameter values save one in his paper Table 1 are supported by references published in 2021 or earlier; the one other was stated as assumption, i.e., without supporting citation. However, his paper was published on April 25, 2022, at a time when the delta variant was all but gone and omicron had widely replaced it. The omicron strain is known to be more infectious than delta (that's how it could replace delta), as well as substantially less virulent than delta and its predecessor strains. Thus, the applicability of the Fisman et al. model and its conclusions to the circulating omicron strain and subsequent omicron substrain variants was already doubtful at the time the paper was published.

22. Second, if the vaccine were to have zero efficacy against infection, then there would be no difference between the vaccinated and unvaccinated groups, and the tendency of the direction of infection between the groups should be balanced, i.e., that the ratio discussed by Dr. Bridle (column AI in the "Patch Model" worksheet of the Excel file, "Ratio of fraction of infections acquired from unvaccinated to fraction of contacts unvaccinated") should be 1.0. I examined this in the Excel model by inserting the value 0 (zero) in cell D11 (Vaccine Efficacy). For the initial time segment rows, this ratio is well below 1.0, but then climbs over longer time frames to greatly exceed 1.0. This suggests that the model itself or its assumed parameter values have an underlying problem which damages the credibility of the model.

23. Third, it was known by April 25, 2022, that the mRNA Covid vaccines were producing appreciable numbers of "breakthrough" infections, i.e., Covid infections after vaccination. It was thus observed that the initial 95% vaccine efficacy against Covid infection proclaimed in December 2020 or shortly thereafter did not last over time. However, the Fisman et al., paper states, "We did not model waning immunity." This is a major flaw of the model, because changing the vaccine efficacy parameter in cell D11 leads to major changes in the values of the Ratio in column AI.

24. Most importantly, the Fisman et al. model assumes a baseline immunity in unvaccinated people of 20% (Table 1 of the paper). There is no cited reference for this value. However, US seroprevalence studies in April-May 2022 (https://covid19serohub.nih.gov/) show that virus nucleocapsid seropositivity (i.e., seropositivity from the virus, not from vaccination) was about 75-85% in the general population and moving upward over time. Putting the value 80% (0.8) in cell D13 (Baseline immunity in unvaccinated) makes all of the Ratio values in column AI almost exactly 1.0, meaning no difference in transmission for vaccinated vs unvaccinated people. However, at values of 81% and greater, as the baseline immunity continued to increase, the Ratio values in column AI are all below 1.0, which indicates according to the model a bias in transmission coming more from the vaccinated, exactly opposite to the conclusions of the paper. This point was made by Dr. Bridle.

25. These four issues demonstrate that the conclusions of the Fisman et al. paper were completely unreliable and were determined by the inappropriate and unrealistic values of the parameters that the authors chose to use in their model. Dr. Bridle's criticism of the paper was therefore scientifically appropriate.

26. In Dr. Bridle's criticism of the Fisman et al. paper, he always refers to the authors as "Fisman et al." and he does not personally attack Dr. Fisman or impugn his reputation.

SOLEMNLY AFFIRMED BEFORE)

A Commissioner for Taking Oaths
Rocco Galati B.A., LL.M., LL.B.

Dr. Harvey Risch

This is Exhibit "A" to the Affidavit of Harvey Risch, affirmed before me on this 11th day of December 2023

_____

A Commissioner for Taking Affidavits

Rocco Galati, , B.A., LL.B., LL.M.

EXHIBIT A: Curriculum Vitae for: HARVEY A. RISCH, M.D., PH.D.

Professor Emeritus of Epidemiology and Senior Research Scientist
Yale School of Public Health, Yale School of Medicine

Business Address: Yale School of Public Health
60 College Street
P.O. Box 208034, New Haven, CT 06520-8034
E-mail: harvey.risch@yale.edu

Education:

Date	*School*	*Degree, Major*
9/80-12/82	University of Washington	Postdoctoral Fellow, Epidemiology
9/76-8/80	University of Chicago	Ph.D., Biomathematics
9/72-6/76	UC San Diego School of Medicine	M.D., Medicine
9/67-6/72	California Institute of Technology	B.S. (Honors), Biology; Mathematics

Professional Appointments:

7/22-	Professor Emeritus of Epidemiology and Senior Research Scientist, Department of Chronic Disease Epidemiology, Yale School of Public Health, Yale School of Medicine, New Haven, CT.
7/01-6/22	Professor of Epidemiology, Department of Chronic Disease Epidemiology, Yale School of Public Health, Yale School of Medicine, New Haven, CT.
1/12-	Director, Molecular Cancer Epidemiology Laboratory and Shared Resource, Yale Comprehensive Cancer Center and Yale School of Public Health
9/06-8/07	Lady Davis Visiting Professor, Department of Community Medicine and Epidemiology, Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel
1/91-6/01	Associate Professor of Epidemiology, Department of Epidemiology and Public Health, Yale University School of Medicine.
1/83-12/90	Epidemiologist-Biostatistician, Epidemiology Unit, National Cancer Institute of Canada, Toronto, Ontario.
7/90-12/90	Associate Professor, Department of Preventive Medicine and Biostatistics, University of Toronto, Toronto, Ontario (Concurrent Appointment).
1/83-6/90	Assistant Professor, Department of Preventive Medicine and Biostatistics, University of Toronto, Toronto, Ontario (Concurrent Appointment).
9/80-12/82	Postdoctoral Fellow, Department of Epidemiology, School of Public Health and Community Medicine, University of Washington, Seattle, Washington.
7/79-8/80	Postdoctoral Fellow, Department of Pathology, University of Chicago, Chicago, Illinois.

h-Index: 111. Publication citations: more than 51,500 research citations as of November 27, 2023.

Awards, Memberships, etc.:

NSF Undergraduate Research Fellowship, Department of Mathematics, California Institute of Technology, Pasadena (6/70-9/70)
General Medicine Stipended Externship, UC San Diego School of Medicine, La Jolla (6-9/73)
Theoretical Biology Predoctoral Traineeship, University of Chicago (9/76-6/79)
Pathobiology Postdoctoral Traineeship (GM 7190), University of Chicago (7/79-8/80)
Cancer Epidemiology Postdoctoral Traineeship (CA 9168), University of Washington (9/80-12/82)
Member, Society for Epidemiologic Research (1982-)
Member, American Society of Preventive Oncology (1984-)
Full Member, Sigma Xi (1986-)
Fellow, American College of Epidemiology (1991-); Member (1984-91)
Member, Yale Cancer Center (1992-), Sections: Cancer Prevention and Control; Gynecologic Oncology; Cancer Genetics
"Best of the AACR Journals" for "Aspirin Use and Reduced Risk of Pancreatic Cancer," one of the most highly cited *Cancer Epidemiology, Biomarkers & Prevention (CEBP)* articles published in 2016 (April 2018) (http://aacrjournals.org/h-a-risch-bio)
The Ruth Leff Siegel Award for Excellence in Pancreatic Cancer Research (2018), $50,000 (http://columbiasurgery.org/pancreas/ruth-leff-siegel-award)
Member, Connecticut Academy of Science and Engineering (2019-)
Highest attention paper ever published in the American Journal of Epidemiology (2020) (https://oxfordjournals.altmetric.com/details/82900954)

Consortia:

BEACON: Barrett's Esophagus and Esophageal Adenocarcinoma Consortium (2005-)
OCAC: Ovarian Cancer Association Consortium (International Consortium of Case-Control Studies of Ovarian Cancer) (2005-)
PanC4: Pancreatic Cancer Case-Control Consortium (2006-); Elected Steering Committee Member (2008-2013, 2014-2017, 2018-2021)
Panscan: Pancreas Cancer Genome-wide Association Study Consortium (2008-)
CIMBA: Consortium of Investigators of Modifiers of BRCA1/2 (2017-)

Research Interests:

Cancer epidemiology and etiology—Pancreas, Ovary, Lung, Breast, Stomach, Bladder, etc.
Cancer genetic epidemiology: polymorphisms, major genes; Hormonal factors and cancer; Occupational/environmental exposures and cancer; Diet and cancer; *Helicobacter pylori* and cancer
Epidemiologic methods; Causal inference; Cancer registration, control and prevention

Teaching Experience:

Advanced Epidemiologic Research Methods (Yale University CDE 619a) (Course developer)
Litigational Epidemiology (Yale University CDE 550) (Course developer)
Fundamentals of Epidemiology (Yale University CDE/EMD 508) (Course co-developer)
Principles of Epidemiology II (Yale University CDE 516) (Course co-developer)
Research Methods in Epidemiology I (University of Toronto CHL 4102f) (Course co-developer)
Research Methods in Epidemiology II (University of Toronto CHL 4105s) (Course developer)
Cancer Epidemiology (University of Toronto CHL 4103f; Yale University CDE 532b)

Trainees

PhD: Advisor to five students; dissertation committee member for 11 students.
MPH or MSc: Advisor to 36 students.

Postdoctoral Fellows: Advisor to 16 fellows.
Visiting Faculty: Host to four visiting professors.

Service Activity:

Grant Review Panels:

Health Canada, National Health Research and Development Program: Epidemiology, Occupational Health and Chronic Disease Panel (1987-91)
NIH External Site Reviewer (1995)
NIH Study Section Regular Member: Epidemiology and Disease Control (EDC2) (1997)
US Army MRMC Ovarian Cancer Research Program Integration Panel Member (1997-2002)
American Cancer Society Extramural Grant Reviewer (1998)
Chair, Epidemiology Grant Review Panel, National Cancer Institute of Canada (2000-2)
Dutch Cancer Society Extramural Research Grant Reviewer (2000, 2001, 2008)
Cancer Council Australia Extramural Research Grant Reviewer (2004)
Pancreatic Cancer Action Network-AACR Career Development Awards Scientific Review Committee (2016-8)
NIH Study Section Member: Epidemiology and Disease Control (EDC2) (2000)
NIH Study Section Member: Epidemiology Special Emphasis Panel (ZRG4, 1998; ZRG1, 2001-3)
NIH Study Section Member: Pancreas SPORE Panel (ZCA1 GRB-V, 2002-3)
NIH Study Section Member: Small Grants Program for Cancer Epidemiology Panel (ZCA1 SRRB-Q, 2003)
NIH Study Section Member: Cancer Genetics Panel (CG) (2004, 2006)
NIH Study Section Member: Cancer Epidemiology, Prevention and Control (NCI-E X1) (2005)
NIH Study Section Member: Breast and Ovarian Cancer Genetics (ZRG1 ONC-U 03M) (2005)
NIH Study Section Member: Gene-Environment Interactions (ZHL1 CSR-D S1 R) (2007)
NIH Study Section Member: Epidemiology of Cancer Member Conflicts (ZRG1 HOP-Q, 2009; ZRG1 PSE-B, 2010)
NIH Study Section Member: Barrett's Esophagus Translational Research Network (ZCA1 SRLB-1 (O1) R, 2011)
NIH Study Section Member: Core Infrastructure and Methodological Research for Cancer Epidemiology Cohorts (ZCA1 SRLB-9 (M2) B, 2013; ZCA1 TCRB-9 (J2) R, 2014; ZCA1 SRBJ (O2) S, 2015)
NIH Study Section Member: Cancer Management, Epidemiology, and Health Behavior (ZCA1 SRLB-B (J1) S, 2013)
NIH Study Section Member: Population Science (U01) (ZCA1 RTRB-Z M1 R, 2016)
Medical Research Council UK External Reviewer (2019)

Journal Editor:

Associate Editor, *American Journal of Epidemiology* (1997-2014)
Editor pro tem, *American Journal of Epidemiology* (2002-2014)

Research Grants Held:

2021-2023 H Zhou (Principal Investigator), J Gelernter, B-Z Yang, V Vasiliou, **HA Risch**. *Genetic Causality of Alcohol Intake and Alcohol Use Disorder on Cancer Risk*. (National Cancer Institute, $257,125 total direct costs over 24 months)

2020-2025 AP Klein (Principal Investigator), G Petersen, D Li, **HA Risch**, P Bracci, S Gallinger, R Hung, M Meng, E Jacobs, J Manjer, M Sund, V Katzke, A Arslan, L Le Marchand, R Milne, R Stolzenberg-Solomon, C Kooperberg, S van den Eeden, J Genkinger, A Schwartz, J Brody, S Lynch, A Tjønneland, X-O Shu, L Amundadottir, K Visvanathan, B Wolpin. *Multi-Ancestry Mapping of Pancreatic Cancer Susceptibility Loci.* (National Cancer Institute, $112,843 total direct costs to Yale subcontract over 60 months)

2018-2020 CY Jeon (Principal Investigator), S Freedland, S Kim, NY Kyeong, TK Nuckols, SJ Pandol, **HA Risch**, B Spiegel. *Predicting the Diagnosis of Pancreatic Cancer by Leveraging Big Data*. (National Cancer Institute, $235,000 total direct costs over 24 months)

2018-2018 ML Irwin (Principal Investigator), L Lu, **H Risch**. *Impact of exercise and diet-induced weight loss on immunosuppression in breast cancer survivors*. (Cynthia Barnett Breast Cancer Foundation, $25,000 total costs over 12 months)

2017-2018 **HA Risch** (Principal Investigator), L Lu. *Feasibility of circulating exosomal proteins in ovarian cancer diagnos*is. (Brozman Ovarian Cancer Foundation, $25,000 total costs over 12 months)

2016-2021 AP Klein (Principal Investigator), P Bracci, S Cleary, S Gallinger, R Hung, D Li, R Neale, S Olson, G Petersen, **HA Risch,** G Scelo. *Validation and Fine-scale Mapping of Pancreatic Cancer Susceptibility Loci.* (National Cancer Institute, $220,000 total direct costs to Yale subcontract over 60 months)

2013-2017 Y Guan, X Ma (Principal Investigators), D Zimmerman, P Diggle, T Holford, **H Risch**, L Mueller, Y Zhang. *New Statistical Methods to Handle Spatial Uncertainty in Cancer Risk Estimation*. (National Cancer Institute, $1,100,000 total direct costs over 48 months)

2011-2016 R Kurman (Principal Investigator), H Berman, L Cope, T Diaz-Montes, M Gauthier, D Huso, D Levine, E Matloff, S Narod, V Parkash, **H Risch**, G Rosner, P Shaw, I-M Shih, R Soslow, R Vang, K Visvanathan, T-L Wang, et al. *Prevention of Ovarian High-Grade Serous Carcinoma by Elucidating Its Early Changes.* (Department of Defense USMRMC, $9,166,162 total direct costs, of which $199,000 total direct to Yale epidemiology subcontract, over 60 months).

2011-2015 AP Klein (Principal Investigator), P Bracci, P Brennan, E Duell, S Gallinger, D Li, R Neale, S Olson, G Petersen, **HA Risch**. *Validation and Fine-scale Mapping of*

Pancreatic Cancer Susceptibility Loci. (National Cancer Institute, $197,000 total direct costs to Yale subcontract over 48 months)

2011-2013 AP Klein, **HA Risch** (Co-Principal Investigators). *Validation and Fine-Scale Mapping of Pancreatic Cancer Susceptibility Loci*. (National Human Genome Research Institute, covers costs of large-scale high-throughput genotyping of collaborative multi-center pancreatic cancer study (see previous grant) at the Center for Inherited Disease Research (CIDR)).

2010-2016 H Yu (Principal Investigator), M Irwin, X Ma, S Mayne, **H Risch**, H Zhao, J Lim. *Epidemiologic Study of Hepatocellular Carcinoma in the US*. (National Cancer Institute, $5,385,000 total direct costs over 60 months)

2010-2014 T Sellers (Principal Investigator), A Berchuck, G Bloom, M Clyde, D Fenstermacher, B Fridley, S Gayther, W Ge, E Goode, E Iversen, H-Y Lin, S Mears, A Monteiro, T Moorman, L Pearce, P Pharoah, C Phelan, **H Risch**, MA Rossing, J Schildkraut, G Trench, Y-Y Tsai. *Follow-up of Ovarian Cancer Genetic Association and Interaction Studies (FOCI)*. (National Cancer Institute, $108,926 total direct costs to Yale subcontract 2012-2014)

2010-2013 CL Pearce (Principal Investigator), JA Doherty, S Gayther, VM McGuire, **H Risch**, MA Rossing, J Schildkraut, TA Sellers, W Sieh, D Stram, G Trench, P Webb, A Whittemore, A Wu. *Identifying Ovarian Cancer Susceptibility Alleles Using Genome-Wide Scan Data*. (National Cancer Institute, $22,500 total direct costs to Yale subcontract)

2009-2014 M Irwin (Principal Investigator), J Dziura, R McCorkle, G Mor, **H Risch**, P Schwartz, H Yu. *Impact of Exercise on Ovarian Cancer Prognosis*. (National Cancer Institute, $2,045,493 total direct costs over 59 months)

2009-2012 T Vaughan, D Whiteman (Principal Investigators), L Bernstein, D Corley, MD Gammon, L Hardie, N Hayward, G Liu, L Murray, O Nyrén, U Peters, B Reid, **HA Risch**, Y Romero, N Shaheen, D Stram, D Van Den Berg, B Weir, A Wu. *Barrett's and Esophageal Adenocarcinoma Consortium Genetic Susceptibility Study*. (National Cancer Institute, $3,750,000 total direct costs over 36 months)

2009-2010 M Goodman (Principal Investigator), A Berchuck, J Chang-Claude, D Cramer, CM Garcia, E Goode, S Krueger Kjaer, R Ness, P Pharoah, **HA Risch**, M Rossing, R Sutphen, K Terry, G Trench, A Whittemore. *Collaborative Genetic Study of Ovarian Cancer Risk*. (National Cancer Institute, $17,419 total direct costs over 12 months, to Yale subcontract)

2007-2014 **HA Risch** (Principal Investigator), Y-T Gao, MS Kidd, H Yu. *Case-Control Study of Pancreas Cancer in Shanghai, China*. (National Cancer Institute, $1,858,377 total direct costs over 75 months)

2007-2012 P Salovey (Principal Investigator), M Irwin, ST Mayne, **HA Risch**. *Promoting Cancer Prevention/Control with Message Framing: III. Extending Tailored Cancer Information Service-Delivered Messages Across the Cancer Continuum*. (National Cancer Institute: $1,525,215 total direct costs over 58 months)

2007-2012 R Neale (Principal Investigator), D Whiteman, J Young, L Fritschi, J Fawcett, P Webb, **H Risch**. *Case-Control Study of Genetic and Environmental Risk Factors for Pancreatic Carcinoma*. (National Health and Medical Research Council (Australia): AU$946,475 total nonacademic direct costs over 60 months)

2007-2011 T Sellers (Principal Investigator), D Ballinger, J Barnholtz-Sloan, ME Colter, Y Huang, E Iversen, J Lancaster, J McLaughlin, S Narod, VS Pankratz, **H Risch**, J Schildkraut, R Sutphen. *Haplotype-Based Genome Screen for Ovarian Cancer Loci*. (National Cancer Institute, $5,726,016 total direct costs over 60 months)

2006-2007 R Neale (Principal Investigator), D Whiteman, L Fritschi, J Young, J Fawcett, P Webb, **H Risch**. *A Case-Control Study of the Environmental and Genetic Causes of Pancreatic Carcinoma*. (Queensland Cancer Fund: AU$258,339 total nonacademic direct costs over 16 months)

2003-2012 **HA Risch** (Principal Investigator), FS Gorelick, D Jain, MS Kidd, ST Mayne, MD Topazian, H Yu. *Case-Control Study of Pancreas Cancer Etiologic Factors*. (National Cancer Institute: $2,578,672 total direct costs over 80 months, in NCE)

2003-2010 H Yu (Principal Investigator), **HA Risch**, ST Mayne, M Irwin, B Cartmel. *Role of Genetic and Lifestyle Interplay in Uterus Cancer*. (National Cancer Institute: $2,185,432 total direct costs over 60 months, in NCE)

2003-2006 SA Narod (Principal Investigator), B Rosen, JR McLaughlin, P Shaw, **HA Risch**. *The contribution of BRCA2 to ovarian cancer*. (National Cancer Institute of Canada: $375,000 total nonacademic direct costs over 36 months)

2002-2005 H Yu (Principal Investigator), **HA Risch**. *DNA Methylation, Aging, and Prostate Cancer Risk*. (National Cancer Institute: $600,000 total direct costs over 48 months)

2002-2006 JP Concato (Principal Investigator), W Li, P Peduzzi, **HA Risch**, D Jain. *Risk of Mortality in Prostate Cancer*. (USVA: $424,000 total direct costs over 48 months)

2001-2007 P Salovey (Principal Investigator), **HA Risch**, ST Mayne, M Morra. *Promoting Cancer Prevention/Control with Message Framing. II*. (National Cancer Institute: $1,324,481 total direct costs over 72 months)

1999-2005 **HA Risch** (Principal Investigator), AE Bale. *DNA Polymorphisms in Ovarian Cancer: Case-Control Study*. (National Cancer Institute: $325,168 total direct costs over 58 months)

1998-2002 JP Concato (Principal Investigator), W Li, P Peduzzi, S Flynn, C Howe, **HA Risch**, D Esrig. *Risk of Mortality in Prostate Cancer*. (USVA: $425,245 total direct costs over 48 months)

1997-2003 **HA Risch** (Principal Investigator), L DiPietro, AF Saftlas, A Duleba, ML Carcangiu. *Case-Control Study of Ovarian Cancer Hormonal Etiology*. (National Cancer Institute: $1,445,806 total direct costs over 70 months)

1997-2000 SA Narod (Principal Investigator), **HA Risch**. *Risk-Factor Analysis of BRCA1 and BRCA2 Carriers*. (National Cancer Institute: $1,228,000 total direct costs over 36 months)

1997-2001 P Salovey (Principal Investigator), **HA Risch**, M Morra. *Promoting Cancer Prevention/Control with Message Framing*. (National Cancer Institute: $498,295 total direct costs over 48 months)

1996-1999 P Salovey (Principal Investigator), **HA Risch**, M Morra. *Message Framing, Persuasion, and Cancer Prevention/Detection*. (American Cancer Society: $198,000 total direct costs over 24 months)

1994-2000 **HA Risch** (Principal Investigator), JR McLaughlin, SA Narod, NJ Risch, EJ Holowaty, BP Rosen, DEC Cole. *Genetic-Epidemiology Study of Epithelial Ovarian Tumors*.

(National Cancer Institute: $799,551 total direct costs over 69 months)

1994-1997 SA Narod (Principal Investigator), HT Lynch, **HA Risch**, DE Goldgar. *The Prevention of Hereditary Breast and Ovarian Cancer*. (National Cancer Institute: $356,875 total direct costs over 34 months)

1992-1996 **HA Risch** (Principal Investigator), ST Mayne, R Dubrow, AB West. *Epidemiologic Study of Esophageal/Gastric Adenocarcinoma*. (National Cancer Institute: $536,163 total direct costs over 43 months)

1991-1992 **HA Risch** (Principal Investigator). *Latency-Temporality Analysis in Case-Control Studies of Chronic Exposures*. (National Institutes of Health (BSRG): $19,000 total direct costs over 12 months)

1990-1991 **HA Risch** (Principal Investigator), GR Howe, R West, LM Strand. *A Record-Linkage Cohort Study of Menopausal Hormone Usage and Endometrial Cancer in Saskatchewan*. (National Health Research and Development Program, Health and Welfare Canada: $50,476 total nonacademic direct costs over 8 months)

1990-1994 JAJ Stolwijk (Principal Investigator), **HA Risch**, ST Mayne, R Dubrow, T Holford. *Cancer Prevention Research Unit for Connecticut at Yale*. (National Cancer Institute: $3,865,000 total direct costs over 60 months)

1989-1993 **HA Risch** (Principal Investigator), LD Marrett, GR Howe, M Jain. *A Case-Control Study of Dietary Factors and Epithelial Ovarian Cancer*. (National Health Research and Development Program, Health and Welfare Canada: $343,766 total nonacademic direct costs over 41 months)

1986-1990 GR Howe (Principal Investigator), **HA Risch**, M Jain, JD Burch, C Wall. *Research Project Support of the NCIC Epidemiology Unit*. (National Cancer Institute of Canada: total nonacademic direct costs $228,093 in 1986-7; $440,454 in 1987-8; $205,617 in 1988-9, etc.)

Selected Scholarly Presentations and Workshops:

11/23 "The Distortion of Evidence-Based Medicine." International Crisis Summit IV, Bucharest, Romania

5/23 "SARS-CoV-2 Vaccine Effectiveness." International Covid Summit III, Brussels, Belgium

10/22 "Plausibility but not Science has Dominated Public Discussions of the Covid Pandemic." Zoom seminar, The Lack of Scientific Freedom: Causes, Consequences & Cures Meeting, Copenhagen, Denmark

3/22 "Legal Considerations for the State of the Covid Emergency, and Why that Emergency No Longer Exists." Zoom seminar, IHU – Méditerranée Infection, Marseilles, France.

3/22 "Early Treatments for Covid-19 and the Trials to Suppress Them." Zoom seminar, PECC – The Israeli Public Emergency Council for the Covid19 Crisis, Tel Aviv, Israel.

1/22 "The War Against Early Covid Treatment." Testimony, US Senate, Washington, DC.

11/21 "Hydroxychloroquine and Other Outpatient Treatments for Covid-19, with Critique of Epidemiologic Methods." Zoom seminar, SIAM Texas-Louisiana Section, UTRGV, South Padre Island, TX

6/21 "Hydroxychloroquine and its Friends." Zoom seminar, IHU – Méditerranée Infection,

Marseilles, France.

11/20 "Randomized Controlled Trials, Hydroxychloroquine and Risk of Hospitalization and Mortality in Patients with Covid-19." Testimony, US Senate Committee on Homeland Security & Governmental Affairs, Washington, DC.

5/19 "Pancreatic Cancer and Diet." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

3/19 "Reducing Mortality of What Will Be the #3 Cause of Cancer Death Two Years from Now." Virus and Other Infection-associated Cancers Research Seminar, Yale School of Medicine, New Haven, CT.

5/18 "New Concepts in Causation." Keynote speaker, Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

2/18 "Risk Factors for Pancreatic Cancer." Yale Pancreas Symposium 2018: Multidisciplinary Management of Pancreatic Cancer. New Haven, CT.

4/17 "Reducing Mortality of what will be the #2 Cause of Cancer Death Four Years from Now." Gastroenterologic Oncology Service, Yale Cancer Center, New Haven, CT.

3/17 "Genomewide Association Study of Pancreatic Cancer in American Jews." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

3/17 "New Markers and Approaches in Predicting Risk of Pancreatic Cancer." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

12/16 "Genomewide Association Study of Pancreatic Cancer in American Jews." Pancreatic Cancer Case-Control Consortium (PanC4) GWAS Study Annual Meeting, Bethesda, MD.

10/16 "Reducing Mortality of Pancreatic Cancer in the International Context." Inaugural Global Oncology Seminar Series speaker, Yale Cancer Center, New Haven, CT.

6/16 "Prevention of Pancreatic Cancer." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Milan, Italy.

1/16 "Reducing Mortality of what will be the #2 Cause of Cancer Death Five Years from Now." Department of Therapeutic Radiation, Yale School of Medicine, New Haven, CT.

10/15 "Reducing Mortality of what will be the #2 Cause of Cancer Death Five Years from Now." Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Rockville, MD.

3/15 "Absolute Risk Models for Pancreatic Cancer." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

12/12 Keynote Speaker, "From Cancer Registration to Cancer Etiology to Cancer Prevention." Cancer Registrars Association of New England Annual Meeting, Norwich, CT.

3/12 "Pancreatic Cancer Risk Models." Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Baltimore, MD.

3/12 Cancer Center Grand Rounds: "*Helicobacter pylori*, ABO Blood Group and the Etiology of Pancreatic Cancer in China and the US." Yale University School of Medicine, New Haven, CT.

9/11 "Etiology of Pancreatic Cancer: Theory and Evidence." Seminar, Division of Chronic Disease Epidemiology, Yale University School of Public Health, New Haven, CT.

3/11 "Genetic Effects and Modifiers of Radiotherapy and Chemotherapy on Survival in Pancreatic Cancer," Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, New York, NY.

1/11 Keynote Speaker, "Why is Pancreatic Cancer Less Frequent in Asia than in the US, in Spite of the Higher Prevalence of Risk Factors in Asia? Observations on the Etiology of Pancreatic Cancer." Japan Epidemiology Association National Meetings, Sapporo, Japan.

1/11 Department Seminar: "*BRCA1* and *BRCA2* Mutations: Population Frequencies and Associations with a Variety of Cancers." Division of Epidemiology and Prevention, Aichi Cancer Center Research Institute, Nagoya, Japan.

1/11 Cancer Center Grand Rounds, "Why is Pancreatic Cancer Less Frequent in Asia than in the US, in Spite of the Higher Prevalence of Risk Factors in Asia? Observations on the Etiology of Pancreatic Cancer." Japan National Cancer Center, Tokyo, Japan.

11/10 Educational Session Seminar, "Gene, environment, and risk-factor interaction in pancreatic cancer." AACR Frontiers in Cancer Prevention Annual International Meeting, Philadelphia PA.

11/10 Workshop Presentation: "*KRAS* variation and risk of ovarian cancer." Biennial meeting of the Ovarian Cancer Association Consortium (OCAC), Bethesda, MD.

5/10 Cancer Center Retreat Seminar, "ABO blood group, *Helicobacter pylori* colonization and pancreatic cancer." Yale University School of Medicine, New Haven, CT.

3/10 "*Helicobacter pylori* colonization, ABO blood group and risk of pancreatic cancer," Pancreatic Cancer Case-Control Consortium (PanC4) Annual Meeting, Bethesda, MD.

7/09 Epidemiology Grand Rounds: "Pancreas Cancer and *Helicobacter pylori* in the U.S. and China." Department of Epidemiology, Shanghai Cancer Institute, Shanghai, China.

3/09 Cancer Center Grand Rounds: "Inconsistencies in Pancreas-Cancer Risk Factors and Disease Incidence Between the U.S. and China: Observations on the Etiology of Pancreas Cancer." Yale University School of Medicine, New Haven, CT.

11/08 Workshop Participant, Defining the Public Health Research Agenda for Ovarian Cancer, Centers for Disease Control, Atlanta, GA.

7/08 Workshop Presentation: "*Helicobacter pylori* and pancreas cancer." Biological and Clinical Risks and Potential Benefits of *Helicobacter pylori* Colonization, Division of Microbiology and Infectious Diseases, NIAID, NIH, Bethesda, MD.

1/08 Research Seminar: "Smoking and lung cancer in women—yet again." Program in Cancer Prevention and Control, Yale Cancer Center, New Haven, CT.

11/07 Workshop Presentation: "*BRCA1* and *BRCA2* Mutations: Frequencies in the General Population of North America and Associations with Breast, Ovary, Stomach, Pancreas and Other Cancers." Nanjing International Symposium of New Frontiers in Cancer Research and Advanced Training Workshop of Cancer Molecular Epidemiology, Nanjing Medical University, Nanjing, China.

10/07 Workshop Presentation: "Why have epidemiology data and outcomes of clinical trials

not correlated?" Third Haifa Cancer Prevention Workshop. CHS National Cancer Control Center, Faculty of Medicine, Technion Israel Institute of Technology, Haifa, Israel.

6/07 Workshop: "Advanced Statistical Methods for Epidemiologic Studies". Department of Community Medicine and Epidemiology, Technion Israel Institute of Technology Faculty of Medicine, Haifa, Israel.

3/07 Ruth and Bruce Rappaport Seminar: "Why Pancreas Cancer is Less Frequent in China than the US, in Spite of the Generally Higher Chinese Prevalence of Risk Factors: Insights on the Etiology of Pancreas Cancer." Faculty of Medicine, Technion Israel Institute of Technology, Haifa, Israel.

2/07 Seminar: "Smoking and lung cancer in women—yet again." Department of Community Medicine and Epidemiology, Technion Israel Institute of Technology Faculty of Medicine, Haifa, Israel.

1/07 Seminar: "Etiologic theories for epithelial ovarian cancer." Department of Community Medicine and Epidemiology, Technion Israel Institute of Technology Faculty of Medicine, Haifa, Israel.

11/06 Seminar: "*BRCA1* and *BRCA2* Mutations: Frequencies in the General Population and Associations with Breast, Ovary, Stomach, Pancreas and Other Cancers." New York University Cancer Center, New York, NY.

2/06 Cancer Center Grand Rounds: "*BRCA1* and *BRCA2* Mutations: Their Frequencies in the General Population and Their Associations with Breast, Ovary, Stomach, Pancreas and Other Cancers," Yale University School of Medicine, New Haven, CT.

11/05 Symposium: "Why Pancreas Cancer is Less Frequent in China than the US, in spite of the Generally Higher Chinese Prevalence of Risk Factors: Insights on the Etiology of Pancreas Cancer." Clinical Oncological Society of Australia annual scientific meeting, Brisbane, Australia (Sponsored by the Queensland Cancer Fund).

11/05 Symposium: "Risks and penetrances of germline *BRCA1* and *BRCA2* mutations for ovarian, breast, stomach, pancreas and other cancers: updated results from the Ontario (Canada) ovarian cancer kin-cohort study." Clinical Oncological Society of Australia annual scientific meeting, Brisbane, Australia (Sponsored by the Queensland Cancer Fund).

6/05 Seminar: "Why Pancreas Cancer is Less Frequent in China than the US, in spite of the Generally Higher Chinese Prevalence of Risk Factors: Insights on the Etiology of Pancreas Cancer." Tumor Registrars Association of Connecticut Quarterly Meeting, Yale-New Haven Hospital, New Haven, CT.

5/05 Seminar: "Why Pancreas Cancer is Less Frequent in China than the US, in spite of the Higher Prevalence of Risk Factors There: Insights on the Etiology of Pancreas Cancer." Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL.

5/02 Symposium: "Genetic Epidemiology of Ovarian Cancer." Ovarian Cancer and High-Risk Women: Implications of Prevention, Screening and Early Detection. University of Pittsburgh, Pittsburgh, PA.

12/01 Seminar: "Prevalence and Penetrance of Germline *BRCA1* and *BRCA2* Mutations in Unselected Ovarian Cancer." Kaplan Cancer Center, NYU School of Medicine, New York, NY.

10/01 Research Seminar: "Prevalence and Penetrance of Germline *BRCA1* and *BRCA2* Mutations in Unselected Ovarian Cancer." Memorial Sloan Kettering Cancer Center, New York, NY.

6/01 Combined Monthly Research Seminar: "Prevalence and Penetrance of Germline *BRCA1* and *BRCA2* Mutations in Unselected Ovarian Cancer." Programs in Ovarian Cancer, Cancer Genetics and Cancer Prevention, Yale Cancer Center, New Haven, CT.

10/00 Departmental Seminar: "Etiology of Epithelial Ovarian Cancer." Department of Public Health Sciences, Fox Chase Cancer Center, Philadelphia, PA.

9/98 "Etiologic Mechanisms in Epithelial Ovarian Cancer," Third International Symposium on Hormonal Carcinogenesis, Seattle, WA.

5/98 Departmental Grand Rounds: "BRCA1 and BRCA2 Mutations in Unselected Ovarian Cancer," Department of Gynecologic Oncology, Yale University School of Medicine, New Haven, CT.

9/97 Departmental Seminar: "Etiologic Mechanisms in Epithelial Ovarian Cancer." Division of Epidemiology, Columbia University School of Public Health, New York, NY.

9/97 "Use of aspirin and other non-steroidal anti-inflammatory drugs and risk of esophageal and gastric cancer." American College of Epidemiology Annual Meetings, Cambridge, MA.

3/97 "Risk Factors for Familial and Hereditary Ovarian Cancer." American Cancer Society Science Writers Seminar, Reston, VA.

2/97 Departmental Grand Rounds: "Etiologic and Histologic Considerations in the Occurrence of Ovarian Cancer." Department of Pathology, Yale School of Medicine, New Haven, CT.

Fax No.: 416-530-8129

Lawyer for the Plaintiff

This is Exhibit "B" to the Affidavit of Harvey Risch, affirmed before me on this 11th day of December 2023

A Commissioner for Taking Affidavits

Rocco Galati, , B.A., LL.B., LL.M.

EXHIBIT B: Risch Comments on the Fisman Affidavit

General observations. One could ask, after three years of observing the Covid pandemic following the large-scale vaccinations that were rolled out, how apparently honest scientists could arrive at almost completely contradictory opinions on the efficacy and safety of the Covid vaccines. In my understanding, this occurred because of different perceptions about what constitutes an appropriate public health management approach. I analogize this as follows. An engineer designs and builds a bridge across a major river. The bridge is 99.99% safe. From the engineer's point of view, achieving 99.99% is extraordinarily good. However, this bridge is on a major roadway and it carries across the river 100,000 cars per day. This means that 0.01% of those cars daily plunge into the river, 10 cars per day, 300 cars per month, 3,650 cars per year, year in and year out. Is that safe enough? Most people, reading media reports about the daily toll of deaths on the bridge, would say that the bridge is dangerous, at the same time that with knowledge of the low personal risk that they would actually face, would have little hesitation about driving across if they had a reason to do so. The point is that the Covid vaccines have not been entirely safe, but from the "engineering" public health viewpoint, have been claimed to be safe enough that they should be widely used. Further, in order to promote the large-scale vaccine uptake, the distinction between "safe enough" and "entirely safe" has been censored from public discussion so that only the latter claim has been promoted. Thus, with 677 million Covid vaccine doses administered as of December 5, 2023 to 270 million Americans, (https://covid.cdc.gov/covid-data-tracker/#vaccinations_vacc-people-booster-percent-pop5), even the hypothetical one-in-a-thousand serious adverse event risk per dose, "99.99% safe," would have amassed 677,000 people who have had serious adverse reactions including death.

That said, previous vaccines have been withdrawn from general use after many fewer serious adverse events (https://www.cnn.com/2020/09/01/health/eua-coronavirus-vaccine-history/index.html). For example, "The CDC said the increased risk was about 1 additional case of Guillain-Barré for every 100,000 people who got the swine flu vaccine. Due to this small association, the government stopped the program to investigate." (https://academic.oup.com/aje/article-abstract/110/2/105/57614)

Additionally, serious vaccine adverse events are not temporally confined to the few days after vaccination but can occur weeks or months or even years later. However, proving that long-term adverse events have been caused by a vaccine can be evidentially challenging. Generally, observational epidemiologic studies provide evidence of such associations, and causal inference is required to draw conclusions of causation based on observed association. This allows proponents of vaccine safety to deny epidemiologic evidence of vaccine harm, by asserting that epidemiologic evidence is somehow not trustworthy or "gold-standard," and that, under the rubric of "evidence-based medicine," only double-blinded randomized controlled trials (RCTs) can be used to infer causation—when they know that such RCTs have not and will not be done because of their large costs as well as the motivation by the vaccine manufacturers and governments not to find evidence of the potential harms of their products.

This circumstance creates the situation where vaccine proponents can reasonably deny that the vaccines cause much harm, while at the same time, compilations of the numbers of individuals seriously harmed by the vaccines can reach into the hundreds of thousands, or maybe even larger numbers as follow-up time increases. In addition, it is easy to cherry-pick or deny evidence in order to artificially

strengthen claims of absolute safety or major harm. Objective science however requires honestly entertaining all relevant evidence (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1898525/), as messy and as subjective as that may be, in coming to conclusions about causation. I have argued extensively (https://onlinelibrary.wiley.com/doi/10.1111/ajes.12539) that RCT studies are not automatically good evidence and can be easily seriously flawed by design or execution, thus evidential reasoning requires evaluation of all relevant evidence, not reliance on RCT studies alone.

Individual Paragraphs in the Fisman Affidavit. Numbers refer to paragraph numbers in the affidavit.

6. "The World Health Organizations COVID-19 Dashboard states that, as of May 2023, there has been over 765,000,000 confirmed cases of COVID-19, and over 6,900,000 deaths. Deaths are believed to be under-reported globally by a factor of 3-4, such that the true death toll is likely over 20 million to date."

The statement about underreporting is unreferenced. On the contrary, deaths *from* Covid are many fewer than deaths *with* Covid, and the former has been what has largely been reported. Studies of adults and children indicate that roughly only half of deaths with Covid are from Covid, and among adults, only some 5% are in people who have no comorbidities that might be responsible for the deaths.

8. "A publication in the journal Lancet estimated that vaccination against COVID-19 had prevented approximately 20 million excess deaths worldwide as of December 2021."

This publication was seriously flawed by the use of inappropriate modeling parameter values.

13. "Dr. Bridle's interview with Ms. Pierson gained international attention because the claims he made were contrary to the overwhelming majority of scientific opinion at the time." ... "Associated Press News article titled "Spike Protein Produced by Vaccine Not Toxic" by Beatrice Dupuy dated June 9, 2021.

This statement has no supporting references about the beliefs of scientists. Further, it does not address evidence about the scientific validity of Dr. Bridle's claims, it cites a news article. Finally, as famously said by philosopher of science Karl Popper, "Studies of what scientists believe have no relation to studies of how nature behaves."

Additionally, the spike (S) protein is known to be toxic. See Moghaddar et al., https://www.mdpi.com/2076-2607/9/10/2167; Fernandes et al., https://www.sciencedirect.com/science/article/pii/S0048969721074222; Hulscher et al., https://www.cureus.com/articles/207654-clinical-approach-to-post-acute-sequelae-after-covid-19-infection-and-vaccination#!/, etc.

14. "Attached hereto as Exhibit "D" is an article from Reuters Fact Check titled "Fact Check No evidence spike proteins from COVID-19 vaccines are toxic" dated June 15, 2021."

See my comment to Paragraph 13. "Fact checks" are not scientific references. Dr. Fisman citing fact checks and news articles is not a serious scientific response.

15. "In my opinion, Dr. Bridle's comments had the potential to harm or halt Ontario's vaccine roll out. Late May and early June 2021 marked a crucial timeframe in the vaccine rollout. At this time efficacy of vaccines against Wuhan-variant COVID-19 as well as the emerging alpha variant remained high, and the

apparent reproduction number of COVID-19 remained low enough, in combination with high vaccine efficacy, that establishment of herd immunity was thought to be possible."

Dr. Fisman bases his assertion that Dr. Bridle's comments could have slowed or halted the Ontario Covid-19 vaccine roll-out on nothing. In reality, the roll-out was not affected by Dr. Bridle's comments. Furthermore, in late May and early June 2021, the US CDC was accumulating large numbers of reports of breakthrough infections (i.e., Covid-19 infections occurring after Covid-19 vaccination; https://data.cdc.gov/Public-Health-Surveillance/Rates-of-COVID-19-Cases-or-Deaths-by-Age-Group-and/3rge-nu2a), and the possibility of such breakthrough infection was generally recognized in public discussions. Because in May 2021, CDC stopped registering breakthrough infections that were not associated with hospitalization or death, the registered breakthrough infections from March through December 2021 were almost entirely serious cases, and the CDC data show that such serious breakthrough infections occurred to some 4.3% of all US vaccinated individuals. Though not officially registered by the CDC, breakthrough infections of lesser seriousness would have been occurring in much larger numbers than the 4.3%.

This means that (a) the Covid-19 vaccines in the time period cited by Dr. Fisman were not all that effective in blocking serious Covid infection, thus not substantially contributing to herd immunity; (b) the need for repeat booster vaccinations in fall 2021 and subsequently shows that herd immunity was not adequately achieved by the vaccine roll-out described by Dr. Fisman; (c) the SARS-CoV-2 Omicron strain sweeping the population from late fall 2021, with its increased infectivity and reduced virulence, infected much larger fractions of the population regardless of vaccination status and thus that wave of infection developed natural immunity and much better herd immunity than had occurred with large-scale vaccination over the previous pandemic period.

17. "Mortality from COVID-19 had declined dramatically in the face of high vaccine uptake by this time [December 2021]." Mortality did not drop because of vaccine uptake but because of the shift from delta to omicron viral strains that was occurring from November/December 2021, and the much lower virulence of the omicron strain.

17. "Ontario having had to establish field hospitals in March 2021 due to overflowing intensive care units."

Whether Ontario had to spend money to create more hospital space is irrelevant. This has no relation to anything that Dr. Bridle said. Furthermore, it was an artificial byproduct of government conspiracies at that time to suppress outpatient usage of hydroxychloroquine, which by mid-2021 was demonstrated to reduce Covid-19 mortality risk by some 75% when started outpatient use by symptom day 5 (https://earlycovidcare.org/wp-content/uploads/2021/09/Evidence-Brief-Risch-v6.pdf).

18. "It was my opinion at the time that COVID-19 vaccination represented an extremely important tool for the health and safety of the Canadian population in the face of a major health crisis."

This assertion has no supporting evidence. The overall case mortality risk of Covid-19 infection at this time was approximately 0.25%, one in 400. That risk would have been reduced by at least 75% by outpatient use of hydroxychloroquine (see previous point). The claim that the infection was a "major health crisis" was a fearmongering approach to the public health management. Further, this assertion

involves no recognition of the possible immediate and long-term health damages that the mass vaccination by a novel and inadequately tested vaccine could cause.

19. "Some claims [of Dr. Bridle's interview], however are not data based."

This is a negative and nonspecific assertion that is impossible to address because it does not specify which claims are in question. It therefore acts as a smear rather than as a statement about scientific evidence.

20. "My intention with this tweet was to warn against the spreading of misinformation to the public in regards to COVID-19 vaccines."

Dr. Fisman has facilely labeled Dr. Bridle's considered statements as "misinformation" without addressing the supposed inaccuracies in those statements. This constitutes a smear and an attempt at censorship rather than a scientific criticism of Dr. Bridle. I discuss the terms “misinformation” and “disinformation” and their use as censorship in my Affidavit.

21. The website Byrambridle.com.

It is beyond my bandwidth to examine all of the discussions posted on this website. I would note however that the anonymous authorship of this website does not rule out major conflicts of interest of its creator, or of malicious intent to damage Dr. Bridle's reputation or career. Dr. Fisman says that he directed "users" to this website, apparently without verifying the expertise of the website's author.

23. "The paper Byram cited doesn't support his claim." Twitter statement by a Dr. Pyle.

No discussion or references in support of this assertion.

24. "An excellent follow for good immune science from @UofGuelphOAC is Dr @glenpyle, who has addressed some of the misinformation in his own tweets."

Dr. Glen Pyle has a total of 55 publications in Pubmed, not a lot for a full professor, and his specialty appears to be cardiac pathophysiology. He does not appear to be a vaccinologist or an infectious diseases expert. Dr. Bridle on the other hand has published 86 peer-reviewed scientific papers and his academic expertise is specifically about vaccines and vaccine immunology.

25. "The purpose of my May 30, 2021 tweet was to direct the public to evidence-based information related to the COVID-19 vaccine."

This is another smear statement directed against Dr. Bridle. The implication that Dr. Fisman is pointing to "evidence-based information" is that Dr. Bridle was presenting information without evidence.

26. "The website debunking Dr. Bridle's Covid-19 vaccine claims has been updated with lots of peer-reviewed science that attests to the safety of vaccines."

I am unclear whether Dr. Fisman was referring in this tweet to all vaccines or to the Covid-19 vaccines. There is substantial evidence accumulating of the excess all-cause mortality associated with the Covid-19 genetic vaccines. At the time of this statement (May 31, 2021), the US VAERS database had already registered thousands of deaths occurring within a few days of Covid vaccination, thus providing evidence of short-term vaccine hazard. These reported deaths are likely to be an undercount of all such deaths occurring within a few days of Covid-19 vaccination.

27. "A friend indicates that Dr Bridle's interview caused his parents to cancel their vaccine appointments. This is not ok."

Dr. Fisman does not follow this comment with any information as to what subsequently happened to the parents. Many people chose not to take the Covid-19 genetic vaccines and did not suffer negative consequences from that choice, even those having gotten Covid. Dr. Fisman's statement here seems more like smear innuendo than statements about scientific evidence.

28 and 29. "The purpose of my May 31, 2021 Twitter thread was to direct members of the public to a website which contained peer-reviewed science-based information on the safety of vaccines."

From my perusal of the Byrambridle.com website, it is mostly innuendo and opinion about Dr. Bridle. There is a discussion of the Ogata et al., 2022 study that examined spike protein circulating in blood by successive days after Moderna mRNA vaccination. There is also a reference to the study by Lei et al., 2021 about effects of the SARS-CoV-2 spike protein on lung tissue cell function. Neither of these studies directly bears upon vaccine safety.

There are also numerous Fact Check citations about the spike protein issue, all denying any possible toxicity of the vaccine spike protein. However, contrary to all these statements, substantial evidence has emerged about the role of the vaccine spike protein in circulating to and causing pathology in various organs. This has been reviewed at length by Parry et al., 2023 (https://www.mdpi.com/2227-9059/11/8/2287).

Finally, mention is made on the Byrambridle.com website of Dr. Bridle's public statement about possible vaccine harm for fertility. The website does not provide scientific rebuttal, only a citation of the CDC webpage, "COVID-19 vaccination is recommended for everyone aged 6 months and older, including people who are pregnant, breastfeeding, trying to get pregnant now, or might become pregnant in the future. This recommendation includes getting boosters when it is time to get one." CDC provides no scientific evidence for this assertion, and the mRNA vaccine RCT studies did not include pregnant women, so Dr. Bridle's statement is not rebutted by any of this.

I find therefore Dr. Fisman's claim that he pointed members of the public to the Byrambridle.com website to provide information about vaccine safety not well justified.

41. "I felt the information Dr. Bridle was sharing could result in Canadians choosing not to get vaccinated for COVID-19. As the information was, and is, in my opinion, not scientifically sound, I wanted to ensure Canadians had access to evidence and data-based information so they could make informed decisions."

I think that Dr. Fisman is disingenuous here. In order for vaccine recipients to make informed choices, they would need thorough and accurate quantitative information on the short- and long-term risks of benefits and harms from taking each dose of the vaccine and of not taking the vaccine. Most of this information was not available to the public. Furthermore, pointing to an anonymous website as if it were an established scientific resource is improper. Finally, large numbers of people were subject to vaccine mandates that required them to accept the mRNA vaccines under threat of loss of employment, military status, etc., thus abrogating all claims to informed consent as part of the vaccination process.

42. "I believed in May and June 2021 that Dr. Bridle's speaking engagements, interviews and articles, posed a risk to the public. Given my professional responsibilities as a medical doctor and an advocate for public health measures on social media, I felt a moral and professional duty to respond to provide my own views and to direct the public to evidence and data-based resources."

Dr. Bridle appears to have asked Dr. Fisman to debate publicly their different scientific opinions in a civil fashion, but Dr. Fisman never responded. Dr. Fisman claims that he never received the emails. Dr. Fisman apparently never tried to engage with Dr. Bridle in such a public discussion either. I note that Dr. Bridle and Dr. Denis Rancourt publicly criticized a paper of Dr. Fisman published in the journal CMAJ (https://www.cmaj.ca/content/194/16/E573), and that the reporter Trish Wood invited Dr. Fisman to discuss his paper and the scientific criticisms, but Dr. Fisman did not respond to that either (https://twitter.com/WoodReporting/status/1520769440593453056).

UNIVERSITY OF GUELPH, JEFFREY WICHTEL, LAURIE ARNOTT, CHARLOTTE YATES, SCOTT WEESE, GLEN PYLE, ANDREW PEREGRINE, DOROTHEE BIENZLE, AMY GREER, DAVID FISMAN, NICK DULEY, JANE OR JOHN DOE JUNIOR SCIENTIST

Defendants

AFFIDAVIT OF DR. STEVEN PELECH

I, Dr. Steven Pelech, of the City of Richmond, in the Province of British Columbia, MAKE OATH AND SAY:

1. I am a professor of Neurology in the Department of Medicine at the University of British Columbia, and as such, have knowledge of the matters contained in this Affidavit.

Section A: Professional, Academic and Research Background as it Relates to COVID-19 Vaccines and Immunity

2. I am a full Professor in the Department of Medicine and Division of Neurology at the University of British Columbia (UBC), where I have been on faculty since 1988. I was one of the founding senior scientists of The Biomedical Research Centre at UBC in 1987. I hold B.Sc. Honours (1979) and Ph.D. (1982) degrees in Biochemistry from UBC. My post-doctoral training was at the University of Dundee with Sir Philip Cohen, and at the University of Washington in Seattle with Nobel laureate Dr. Edwin Krebs. Attached and marked as Exhibit A is a copy of my *curriculum vitae*.

3. I have previously completed several courses in microbiology, immunology and virology during my B.Sc. undergraduate training, and I was a founding and senior scientist for six years at The Biomedical Research Centre, which was an immunology focused institute located at UBC, where I have remained on faculty as a professor in the Department of Medicine for 35 years. Over a dozen of my scientific research articles have appeared in immunology specialty journals, including the *Journal of Immunology, Blood, Molecular Immunology, Immunology, Infectious Immunology, Cancer Immunology and Immunotherapy*, *International Journal of Vaccine Theory, Practice and Research* and *Vaccines*. These studies document some of my work to understand the molecular mechanisms by which different immune cells, including macrophages, T and B cells become activated. My lectures in formal graduate level courses include teaching in immunology, virology and bioinformatics at UBC. I have presented my research at over 100 national and international scientific conferences. My UBC lab and spin-out companies have been engaged in the production and testing of over 1600 antibodies for our internal research programs and for commercial sale for over 28 years. My independent research has routinely involved for over 35 years, the use of standard and novel immunological techniques developed in my lab, such as Western blotting, dot blotting, antibody microarrays, reverse lysate microarrays and epitope mapping for determination of where antibodies specifically bind their targets.

4. I have authored over 260 scientific publications in peer-reviewed journals and book chapters about cell communication systems important for cell survival and function and implicated in the pathology of cancer, diabetes, neurological and immunology-related diseases. Awards I have received include the 1993 Martin F. Hoffman Award for Research at UBC, and the 1993 Merck Frosst Canada Prize from the Canadian Society of Biochemistry and Molecular

Biology. I was the 2001 Distinguished Lecturer for the Faculty of Medicine at UBC for the Basic Sciences. I have served on grant review panels for the US National Institutes of Health, the Canadian Institutes for Health Research, the National Research Council of Canada, the Michael Smith Health Research Foundation, Genome Alberta, Genome Prairie, the Canadian National Cancer Institute, the Canadian Heart and Stroke Foundation and the American Heart Association, and I have acted as an external reviewer for 22 other agencies including the U.S. National Science Foundation and the Israel Science Foundation. I have also been an external reviewer for 28 different scientific journals, including those that are focused on immunology and vaccines.

5. I was the founder and president of Kinetek Pharmaceuticals Inc. from 1992 to 1998, and the founder, president and chief scientific officer of Kinexus Bioinformatics Corporation from 1999 to the present. Kinetek was engaged in the development of drugs that inhibit protein kinases, primarily for oncology application and diabetes. Kinexus has produced over 1600 antibody products against cell regulatory proteins, and employs these antibodies in novel, immunology-based, high throughput methods such as antibody microarrays to monitor cell communication systems in biological specimens from over 2000 academic and industrial clients in over 35 countries over the last 22 years. **These antibody products include those that specifically recognize parts of the SARS-CoV-2 virus, including its Spike, Nucleocapsid, Membrane and other Non-structural (NSP) proteins encoded by the genome of this virus.**

6. My expertise has been sought in over 14 court cases in Canada and South Africa as an expert witness specifically with respect to understanding the immunological mechanisms by which a natural immune response is elicited by SARS-CoV-2, the causative agent of COVID-19, and

the immunity afforded by the lipid nanoparticle Spike RNA- and adenovirus Spike DNA-based COVID-19 vaccines. This has been informed, in part, by clinical studies undertaken in the last three (3) and a half years at my company Kinexus in which we have investigated the nature and production of antibodies against the 28 different proteins that constitute the SARS-CoV-2 virus particle, by examination of blood samples from over 4500 participants from across Canada. In this independent ethics review board approved clinical study, I am the lead investigator, and I have been in direct communication with all of the participants. Some of our preliminary findings have already been published in *JCI Insights*, which is the flagship journal of the American Society for Clinical Investigation in 2021.[1] Additional manuscripts that document our SARS-CoV-2 antibody testing study are currently in preparation, and we recently finished a second antibody testing study to determine the extent of immunity against the Omicron variants and the duration and effectiveness of the COVID-19 vaccines.

7. I have also been investigating the use of drugs to inhibit the replication of the SARS-CoV-2 virus in infected host cells. My expertise on enzymes known as protein kinases has permitted me to predict and then verify that compounds that inhibit a protein kinase known as GSK3-beta can block the production of the Spike of the virus, and assembly of SARS-CoV-2 virus particles. A provisional patent based on this work has already been filed with the University of British Columbia (UBC) and manuscript that describes this work has been published.[2] Presently, I have been involved in the development of a short peptide that binds with high

[1] Majdoubi, A., Michalski, C., O'Connell, S.E., Dada, S., Narpala, S. *et al*. (2021) A majority of uninfected adults show pre-existing antibody reactivity against SARS-CoV-2. *JCI Insight* 6(8): e14631. https://doi.org/10.1172/jci.insight.146316

[2] Shapira, T., Rens, C., Pichler, V., Rees, W., Steiner, T., Jean, F., Winkler, D.F.H., Sarai, I., Pelech, S., Av-Gay, Y. (2022) Inhibition of glycogen synthase kinase-3-beta (GSK3β) blocks nucleocapsid phosphorylation and SARS-CoV-2 replication. *Molecular Biomedicine* 3, 43. https://doi.org/10.1186/s43556-022-00111-1

affinity to the NSP15 protein of SARS-CoV-2, which may block the replication of this virus and also serve as a therapeutic for treatment of COVID-19. I have also spearheaded the development commercial antibodies against many of the SARS-CoV-2 proteins and verified their utility in another published scientific article in the peer-reviewed journal Microbial Factories.[3]

8. In addition to the direct study of the SARS-CoV-2 and immune responses to this virus in people, I am also a co-founder and vice president of the Canadian Covid Care Alliance (CCCA) and very active within this organization. The CCCA's membership include over 600 biomedical scientists, medical doctors and other health practitioners, and the CCCA examines the scientific literature and data from public health authorities to ascertain the threat of COVID-19 and the various strategies available to mitigate its effects. In my capacity as the co-chair of the Scientific and Medical Advisory Committee (SMAC) of the CCCA, I oversee the activities of a panel of over 30 scientists and medical doctors that seeks to provide a scientific evidence-based and balanced, independent, but critical assessment of health care policies related to COVID-19. This Committee has met weekly over the last two (2) and half years by Zoom, but typically has daily correspondences by e-mails. The fruits of our efforts are published on the CCCA website (www.canadiancovidcarealliance.org) and in peer-reviewed scientific journals. In particular, I was a coauthor on a CCCA report that critiqued the original 6-months clinical study performed by Pfizer/BioNTech on their BNT162b2 RNA vaccine,[4] a published review about COVID-19 vaccines and pregnancy in the peer-reviewed

journal *Vaccines*,[5] and another manuscript published in the peer-reviewed journal *International Journal of Vaccine Theory, Practice and Research*.[6] In addition, I am a coauthor on several other publications that have been posted on the CCCA website that relate to the manufacturing and quality issues associated with the BNT162b2 mRNA COVID-19 vaccine,[7] the efficacy and safety of the BNT162b2 mRNA COVID-19 vaccine based on phase III trial results,[8] and the vaccination of children with COVID-19 vaccines.[9] I am the senior editor of an upcoming book "Down the COVID-19 Rabbit Hole: Independent Scientists and Physicians Unmask the Pandemic." In addition to co-editing the book with Dr. Christopher Shaw (another professor at UBC), I have personally written about half of the chapters in this 700-page manuscript with over 1800 references, along with 24 other authors.

9. It is in my capacity as the co-chair of the CCCA Scientific and Medical Advisory Committee that I have come to know Dr. Bridle professionally as a member of our committee. I have not interacted with Dr. Bridle socially, and I have not met him in person, but only by Zoom meetings. I have also seen and heard him speak on podcast videos. I have remained highly impressed by his tireless and ongoing commitment to apply his excellent critical thinking skills, and his deep knowledge of immunology, vaccinology and virology, to the handling of the COVID-19 pandemic in our committee discussions and to the general public. I have never witnessed any occasion during this time when I was concerned that he might be spreading "misinformation." Like all of the members of the Scientific and Medical Advisory Committee, he is a strong proponent of vaccination to reduce the spread of infectious diseases. However, like the rest of the committee, including myself, he has genuine concerns about the production, testing, efficacy and safety of COVID-19 genetic vaccines, such as the lipid nanoparticle/RNA COVID-19 vaccines from Pfizer/BioNTech (BNT162b2; Comirnaty) and Moderna (mRNA-1273; Spikvax), and the adenovirus COVID-19 vaccines from AstraZeneca (Vaxzevria) and Johnson & Johnson (Jcovden).

Section B. Scope of Opinion

11. For the preparation of this affidavit, I have listened to Dr. Bridle's interview with Ms. Alex Pierson, on her Global News radio show on May 28th, 2021. I have further reviewed the May 26, 2023, affidavit of Dr. David Fisman, filed in this motion. In my affidavit, I specifically and scientifically address:

    a. Whether what Dr. Bridle stated in the Global News interview with Ms. Alex Pierson on her radio show on May 28th, 2021 was scientifically accurate.

b. Whether Dr. Fisman's statement that Dr. Bridle's statements were "misinformation", are true or tenable?

c. Whether Dr. Fisman, based on his qualifications and expertise, was appropriately qualified to determine that Dr. Bridle's statements could be construed as "misinformation?"

d. The (potential) impact of Dr. Fisman's behaviour/conduct to Dr. Bridle's research funding and career?

Section C. Dr. Bridle's Claims were Not Misinformation

12. In the Alex Pierson interview, Dr. Bridle made the following specific claims:

a. The lipid nanoparticles of the Pfizer.BioNTech COVID-19 travel from the site of injection in the deltoid muscle of the arm to organs throughout the body, including the spleen, bone marrow, liver, adrenals and ovaries. This is accurate and was evident in a Pfizer study that was submitted to the Japan Regulatory Agency.[10]

b. In a study by Ogata *et al*. (2021),[11] it was shown that in a study of 13 young health care workers following injection of the Moderna COVID-19 vaccine, there was detection Spike protein in many of their blood samples.

c. The Spike protein produced from inoculation of the COVID-19 genetic vaccines was a toxin that caused blood clotting and abnormal bleeding.

[10] "SARS-CoV-2 mRNA Vaccine (BNT162, PF-07302048) 2.6.4 薬物動態試験の概要文 (translation: "Summary of pharmacokinetic study")" https://pandemictimeline.com/wp-content/uploads/2021/07/Pfizer-report_Japanese-government.pdf

[11] Ogata, A.F., Cheng, C.A., Desjardins, M., Senussi, Y., Sherman, A.C., *et al.* (2022) Circulating Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) vaccine antigen detected in the plasma of mRNA-1273 vaccine recipients. Clin Infect Dis. 74(4):715-718. doi:10.1093/cid/ciab465

d. The COVID-19 mRNA vaccines are able to transfer into breast milk following vaccination of lactating mothers.

e. The Canadian Blood Services uses blood from recently COVID-19 vaccinated individuals, which might permit the transfer of the vaccine lipid nanoparticles and/or Spike protein to recipients.

f. The possibility exists, since the COVID-19 mRNA vaccine lipid nanoparticles concentrate in the ovaries following inoculation, that this might lead to infertility.

13. All of Dr. Bridle's assertions and concerns at the interview were scientifically grounded, accurate, and supported by the scientific evidence and not "misinformation" nor "disinformation." I will address each of these claims below.

- **Biodistribution of COVID-19 RNA/Lipid Nanoparticle Vaccines**

14. The specific document that Dr. Bridle referred to in the Alex Pierson interview was translated from Japanese to English in a report submitted to the Japanese government by Pfizer that outlined the results of a 48 hour-post inoculation study performed with rats that were injected with the same lipid nanoparticles used in their COVID-19 vaccine formulation, but was missing the Spike-encoding RNA.[10] Within 48 hours of injection, 76% of the lipid nanoparticles had left the site of injection, and especially concentrated in the liver, spleen, adrenal glands and ovaries, although much wider distribution was documented. The data could also be retrieved from a response (see page 47) from the European Medicine Agencies to what appears to be exactly the same biodistribution study that was submitted to the Japan Regulatory Agency.[12] Di *et al*. (2022) have also noted the wide-spread distribution of COVID-

[12] Comirnaty European Public Assessment Report. Dec. 21, 2020. European Medicines Agency. Retrieved from https://www.ema.europa.eu/en/documents/assessment-report/comirnaty-epar-public-assessment-report_en.pdf

19 RNA vaccine lipid nanoparticle following their injection of mice.[13] This study also demonstrated that the surrogate luciferase gene that replaced the Spike RNA in the lipid nanoparticles was clearly being produced in these other organs. Such studies have not been performed in humans for ethical reasons.

15. Nevertheless, there are numerous reports of the presence of vaccine Spike mRNA and protein that are detectable for weeks and even months in the blood and lymph nodes of vaccinated individuals.[14] [15] [16] [17] Vaccine mRNA encoding Spike protein was found circulating in plasma of patients 15-28 days after administration of the Moderna and Pfizer-BioNTech vaccines.[11] [14] [18] [19] Both vaccine mRNA and Spike protein were detected in lymph nodes 60 days post vaccination,[15] and Spike protein persisted in circulating exosomes isolated from patients 4 months after vaccination.[17]

16. The expression of the Spike protein in diverse organs and tissues following autopsy of people who died following COVID-19 vaccination has also been revealed by immunohistochemical examinations. This became first apparent in the scientific literature from immunohistochemistry studies performed by German pathologist Dr. Michael Mörz on a deceased male, 76-years-old Parkinson's patient who died within 3 weeks of receiving his third inoculation with the BNT162b2 mRNA.[20] Using specific antibodies to detect either the Spike or Nucleocapsid proteins of SARS-CoV-2 in tissue slices, only the Spike protein was detected within the foci of inflammation in both the brain and the heart, particularly in the endothelial cells of small blood vessels. No Nucleocapsid protein could be detected at these sites, which ruled out an actual SARS-CoV-2 infection to account for the Spike protein detection. From inspection of the foci of Spike protein detected in the brain and heart slices, it was evident that the Spike protein has been locally produced, almost certainly from the spread of the lipid nanoparticles in the COVID-19 vaccines.

17. Even more extensive analyses of 75 people in the Reutlingen area that had died following COVID-19 vaccinations were performed by another German pathologist Professor Arne Burkhardt and his international team of nine other pathologists, coroners, biologists and chemists. These deceased individuals (40 men and 35 women with a median age at death of 65.7 years) had died one day to ten months after their last COVID-19 vaccination, most commonly with the BNT162b2 vaccine. The cause of death for 68 of them was previously ruled as "natural" or "uncertain" by pathologists or coroners at the time of death (only 7 were said to be possibly linked to COVID-19 vaccination), and 19 of these cases were examples of

[20] Mörz, M. (2022) Case report: Multifocal necrotizing encephalitis and myocarditis after BNT162b2 mRNA vaccination against COVID-19. Vaccines (Basel). 10(10):1651. doi: 10.3390/vaccines10101651

unexpected Sudden Adult Death Syndrome. Dr. Burkhardt's team subsequently determined that 77% of these deaths (21 beyond reasonable doubt and 37 probably) were caused by their COVID-19 vaccination. The CCCA Scientific and Medical Advisory Committee was privileged to review many of Professor Burkhardt's findings with him, and a video copy of his presentation is posted on the CCCA website.[21] In the immunohistochemistry images of the various tissues retrieved from the deceased individuals that Dr. Burkardt's team analyzed, it was apparent that the Spike protein was widely and highly expressed in many of the tissue samples, in the absence of any detectable Nucleocapsid protein from an active SARS-CoV-2 infection. Furthermore, in these images it was clear that there was infiltration of immune cells and clear tissue pathology. This included, as observed by Dr. Matthew Mörz with the deceased Parkinson's patient, Spike protein expression, immune cell presence and cellular damage in the heart muscle. These findings are in line with the expected inflammatory responses that would arise from the expression of Spike protein on the surface of cells. Significantly, the detection of Spike protein was evident in deceased that had been vaccinated even 10 months after their last inoculation before death, and the Spike protein production was concentrated in the tissue images at the sites of destruction. This means that the detected Spike protein was not simply produced at the site of injection in the muscle and released from the muscle cells into the circulation, but rather the lipid nanoparticles or adenoviruses in the vaccines traveled throughout the body and produced the Spike protein locally.

18. Collectively, these studies fully support Dr. Bridle's original assertion that the COVID-19 RNA vaccine lipid nanoparticles do not remain at the site of injection, but rather travel

[21] Burkhardt, A. (2023) The underlying pathology of Spike protein biodistribution in people that died post COVID-19 vaccination. Canadian Covid Care Alliance. Retrieved from https://www.canadiancovidcarealliance.org/all/professor-arne-burkhardt-video/

throughout the body. In paragraphs 13 and 14 of Dr. Fisman's affidavit, he simply refers to website reports posted by "facts checkers" to discredit Dr. Bridle's claims. In particular, he cited an Associated Press News article by Beatrice Dupuy,[22] and by Reuters.[23] However, none of these actually dispute the fact that the vaccine lipid nanoparticles distribute throughout the body within a day of injection and permit the wide-spread production of Spike protein.

19. In retrospect, this widespread distribution was entirely predictable, as the lipid nanoparticles were originally designed to pass through the blood brain barrier.[24] The intramuscular injection of COVID-19 vaccines is well known to release at least a small proportion (2% or more) of the lipid nanoparticles directly into the blood stream. A standard protocol of 'aspiration' during intramuscular injection of COVID-19 vaccines was generally abandoned, since it slightly increases the less of pain during administration.[25] While this might seem to be a small proportion of the vaccine that gets directly into the blood stream, it is important to recognize that the standard dose of the Moderna COVID-19 vaccine contains 100 micrograms of RNA. This corresponds to tens of trillions of individual nanoparticles per injection. Each nanoparticle contains 5 to 10 copies of Spike RNA molecules that have been genetically modified to be highly stable. Each RNA molecule can be used to generate a hundred or more copies of Spike protein, which ultimately gets deposited on the surface of cells that take up

the lipid nanoparticles. Since the lipid nanoparticles have no targeting structures on their surfaces, they will fuse and deliver their RNA contents into any cell that they happen to pass by. The consequence of this is that the cells of the immune system will attack any of the body's cells that expresses the Spike protein on their surface, often killing these cells. In the cases of neurons in the brain and spinal cord, and heart muscle cells, these are not replaceable by generation of new neurons or heart muscle cells.

- **Detection of Spike Protein in Blood Samples**

20. In his radio conversation with Alex Pierson, Dr. Bridle referred to the study of 13 young health care workers by Ogata *et al*. (2021),[11] in which was detected the presence of Spike protein in blood samples retrieved from several of the participants. To understand this study, it is important to know a few facts about the structure of the Spike protein produced by the COVID-19 RNA and adenovirus vaccines. The resultant Spike protein is cleaved into two subunits, S1 and S2, following the production of the protein inside of transfected cells. The S1 subunit features the Angiotensin Converting Enzyme 2 (ACE2) binding portion of the Spike protein. ACE2 acts as the main receptor for the SARS-CoV-2 virus binding and entry as it is expressed on the surface of host cells. The S2 subunit contains a transmembrane domain region and a palmitic fatty acid modification near the backend of the protein. These anchor the Spike protein to the surface lipid membrane of the cell in a complex of three S1 and three S2 subunits that are highly intertwined. However, if a portion of the RNA in the COVID-19 vaccines is incomplete, this may result in truncated versions of Spike protein that are not full-length and can be missing the membrane anchoring portion. Such incomplete Spike protein complexes can be easily released from cells into the lymphatic and blood systems. Since these truncated Spike proteins still retain the ACE2 binding domain of the S1 subunit, they may still

bind and engaged ACE2 and other receptors that the Spike protein can also recognize (such as Neuropilin[26]) and have functional consequences.

21. In the Ogata *et al*. (2021) study,[11] 3 of the 13 Moderna COVID-19 vaccinated individuals had detectable full length Spike protein in their blood plasma with their first injection and 11 of them had detectable S1 subunit protein. While the S1 protein was detectable in the plasma within the first day of injection, peak levels were detectable 5 days after the first inoculation. Thereafter, the detectable Spike and S1 levels declined, which was attributed to the production of antibodies against these target proteins that quickly cleared them from the circulation. Due to such antibodies, the presence of these proteins was not detectable after the second dose of the vaccine. In the cited Associated Press News article by Beatrice Dupuy,[22] and by the article by the Reuters' facts checkers,[23] the presence of the Spike and S1 proteins in the plasma samples was dismissed, since a very sensitive assay was needed for their protection. However, it should be appreciated that typical blood volume in the circulation alone is over 4 litres, so a high degree of dilution is expected of released Spike and S1 proteins into the plasma, especially since the vast majority of the Spike protein is supposed to remain anchored to cells. In principle, there should never have been any Spike protein evident in the plasma samples from blood. As such, Dr. Bridle accurately reported the findings of this study, which are corroborated by the other studies cited in paragraph 16 earlier in my affidavit.

- **Spike Protein is a Toxin that caused Blood Clotting and Abnormal Bleeding**

22. Apart from contaminating DNA[27], double-stranded RNA[28] and endotoxin[29] along with other undesirable ingredients[30] [31] in the COVID-19 RNA vaccines, the Spike protein produced from the modified RNA can be toxic itself. This was evident in a study by Rong *et al.* (2023),[32] in which recombinant Spike protein was injected into the tail vein of mice. The S1 the subunit of the Spike protein was localized to virtually every organ, including prefrontal cortex and in narrow niches of the brain, where Spike protein persisted for 28 days, causing cell death and neuronal injury.

23. As discussed above in paragraph 21, impurities in the RNA vaccines that result in truncated Spike protein may be released more readily into the circulation from vaccine transfected cells if they are missing the transmembrane domain region and the palmitic fatty acid modification. At the time of conditional approval of the vaccines, the allowable limits for fragmented mRNA

were up to 45% in the final product.[33] Despite alteration of the sequence in the Spike protein with two serine residues replaced by proline residues from mutation of mRNA sequence, which locks the Spike protein in a prefusion state, the Spike protein should still be able to engage angiotensin-converting enzyme 2 (ACE2) and other Spike receptors that are expressed on cells of the body. ACE2 is important for reducing blood pressure through its ability to degrade the hormone angiotensin 2. The Spike protein binding to ACE2,[34] TMEM16F,[35] and CD42b receptors on platelets and stimulate their activation and aggregation,[36] and contribute to thrombosis (blood clotting) and thrombocytopenia (reduction of production of platelets), which are known risks associated with COVID-19 vaccines.[38]

24. Due to issues of blood clotting and vaccine-induced immune thrombotic thrombocytopenia (VIIT) following injection with the AstraZeneca COVID-19 adenovirus vaccine, the National Advisory Committee on Immunization (NACI) in Canada recommended a pause for using this vaccine in people under 55 years of age.[39] Later, Ontario Public Health suspended offering the AstraZeneca vaccine on May 11, 2021 out of caution due to the increased risk of blood

clots of 1 in 55,000 that were vaccinated.[40] In the Canada Adverse Events Following Immunization System (CAEFIS), the two major safety signals for COVID-19 vaccines that were acknowledged as confirmed were thrombosis (blood clotting) with thrombocytopenia syndrome (low platelet count in blood) and myocarditis/myopericarditis.[41]

25. It should be appreciated that the COVID-19 RNA vaccines have also been linked with elevated D-dimer and VITT as exemplified in cases studies of individuals that were vaccinated with either the Pfizer/BioNTech or Moderna vaccines for COVID-19.[42] [43] In a systematic review of the literature, Tan *et al.* (2023)[44] reported:

> *"Studies included in this review included 10 cohort studies and 57 case report or case series. A total of over 24,000 thrombotic events have been reported, the majority of which have been associated with adenoviral vector-based vaccine, particularly AstraZeneca (5 in 100,000 up to 6 in 1000), followed by Janssen (8–30 in 1,000,000 doses), Pfizer (6 in 1,000,000 up to 1 in 1000 doses) and Moderna (4 in 10,000,000)."*

26. Soon after the COVID-19 genetic vaccines were introduced into the general population, there were many anecdotal reports that vaccinated women were experiencing prolonged menstrual

cycles and heavier menstrual bleeding, even including in some post-menopausal women.[44] [] A Facebook group featured over 20,000 testimonials regarding abnormalities in menstrual cycles before it was deleted in an act of censorship. Since then, other organizations such as My Cycle Story have emerged to record such experiences.[45] Initially, these claims were largely dismissed by health officials. However, this has been investigated in several prospective studies, almost all of which support the finding of abnormal menstrual periods with COVID-19 vaccination, although to different degrees of severity.

27. In the Pregnancy Study Online (PRESTO) with 1,137 participants from the US and Canada, who were trying to conceive without fertility treatment, it was noted that the women "had [a] 1.1 day longer menstrual cycles after receiving the first dose of COVID-19 vaccine and 1.3 day longer cycles after receiving the second dose."[46] The authors "*did not observe strong associations between COVID-19 vaccination and cycle regularity, bleed length, heaviness of bleed, or menstrual pain*." The participants were followed over 5 menstrual cycles and of the 437 that were vaccinated at least once, 93% of them received a COVID-19 RNA vaccine (60% Pfizer/BioNTech vaccine and 32.9% Moderna vaccine). Another larger US prospective study with 3,959 participants also noted a slight increase in the length of the menstrual cycle, but no change in the duration of the menses period.[47]

28. Another prospective study, the Nurses' Health Study 3, with 3858 premenopausal American and Canadian female nurses that were not taking hormonal contraceptive medications, similarly found a change to longer menstrual cycles within the first 6 months after COVID-19 vaccination.[48] This was particularly evident among women who took the COVID-19 adenovirus vaccines, and whose cycles were short, long, or irregular before vaccination; by contrast SARS-CoV-2 infection did not produce any changes in menstrual cycle characteristics.[48]

29. The delay in menstrual periods in recently vaccinated women was found to be reduced if they were taking hormonal contraceptive medications in a study with 1273 British and French women, and the study authors speculated "*that menstrual changes following vaccination may be mediated by perturbations to ovarian hormones*."[49] In this study, for participants with "progesterone-only contraceptions", their periods post-vaccination were significantly heavier than usual. Heavier menstrual bleed was also more evident in older women following vaccination.[49]

30. Other studies have also described heavier and/or more prolonged bleeding during menses in woman after COVID-19 vaccination. A Norwegian study of 3972 women between 18 to 30 years of age found that while menstrual disturbances were common regardless of vaccination status, "increased risks of prolonged bleeding, shorter interval between menstruations, and stronger pain during menstruation were also observed after both doses" of COVID-19

[48] Wang, S., Mortazavi, J., Hart, J.E., Hankins, J.A., Katuska, L.M., *et al.* (2022) A prospective study of the association between SARS-CoV-2 infection and COVID-19 vaccination with changes in usual menstrual cycle characteristics. vaccines.[50] This research group also tracked unexpected vaginal bleeding and COVID-19 vaccination in non-menstruating women both 3 months before and then after SARS-CoV-2 mRNA BNT162b2 vaccination.[51] The authors noted:

> "*Among 7725 postmenopausal women, 7148 perimenopausal women, and 7052 premenopausal women, 3.3, 14.1, and 13.1% experienced unexpected vaginal bleeding during a period of 8 to 9 months, respectively. In postmenopausal women, the risk of unexpected vaginal bleeding (i.e., postmenopausal bleeding) in the 4 weeks after COVID-19 vaccination was increased two- to threefold, compared to a prevaccination period. The corresponding risk of unexpected vaginal bleeding after vaccination was increased three- to fivefold in both nonmenstruating peri- and premenopausal women*."[51]

31. Another study included women aged 18-50 years without known gynecologic comorbidities who regularly monitor their menstruation through electronic calendars.[52] A total of 219 women in this study met the inclusion criteria. Of these, 51 (23.3%) experienced irregular bleeding following the vaccine. Almost 40% (n = 83) of study participants reported a menstrual change following vaccination with the BNT162b2 SARS-CoV-2 mRNA vaccine.

32. Likewise, in a cross-sectional European study with 14,153 women, who were double COVID-19 vaccinated at least three months before, 78% of them (many of them older or smokers)

---

[50] Trogstad, L., Laake, I., Robertson, A.H., Mjaaland, S., Caspersen, I.H., *et al.* (2023) Heavy bleeding and other menstrual disturbances in young women after COVID-19 vaccination. Vaccine. 41(36):5271-5282. doi:10.1016/j.vaccine.2023.06.088

[51] Blix, K., Laake, I., Juvet, L., Robertson, A.H., Caspersen, I.H., *et al.* (2023) Unexpected vaginal bleeding and COVID-19 vaccination in nonmenstruating women. *Science Advances*. 9(38):eadg1391. doi:10.1126/sciadv.adg1391

[52] Lessans, N., Rottenstreich, A., Stern, S., Saar, T.D., Porat, S., Dior, U.P. (2023) The effect of BNT162b2 SARS-CoV-2 mRNA vaccine on menstrual cycle symptoms in healthy women. Int J Gynecol Obstet. 160(1):313-318. doi: 10.1002/ijgo.14356

reported premenstrual symptoms including "increased fatigue (43%), abdominal bloating (37%), irritability (29%), sadness (28%), and headaches (28%)" and the predominant changes were "more menstrual bleeding (43%), more menstrual pain (41%), delayed menstruation (38%), fewer days of menstrual bleeding (34.5%), and shorter cycle length (32%)."[53]

33. In a large US study with 39,129 participants that were followed for 3 months after receiving two doses of a COVID-19 vaccine and had not contracted COVID-19, the authors reported:[54]

> *"42% of people with regular menstrual cycles bled more heavily than usual, while 44% reported no change after being vaccinated. Among respondents who typically do not menstruate, 71% of people on long-acting reversible contraceptives, 39% of people on gender-affirming hormones, and 66% of postmenopausal people reported breakthrough bleeding. We found that increased/breakthrough bleeding was significantly associated with age, systemic vaccine side effects (fever and/or fatigue), history of pregnancy or birth, and ethnicity."*

34. As mentioned earlier, hormonal changes induced by the COVID-19 vaccines appeared to partly underlie the menstrual changes observed with vaccination. Since the Pfizer COVID-19 vaccine lipid nanoparticles have been shown to accumulate in the ovaries, it is possible that this might contribute to the abnormal menstrual cycles in some fertile women following vaccination. The hypothalamus and pituitary glands in the brain and the ovaries hormonally

control the menstrual cycle, so damage to the ovaries from an inflammatory attack might contribute to this effect, as well as platelet depletion following blood clotting induced by the COVID-19 vaccines.

35. It is important to appreciate that a female is born with all of the oocytes that she will have in her lifetime, and once she is fertile after puberty, she will have approximately 400 periods in which one (and sometimes more) oocyte is converted to a fertilizable egg by the process of meiosis. The vast majority of oocytes die off without undergoing meiosis during a woman's fertile life. Menopause occurs in women when they deplete their supply of oocytes. Inflammatory damage to the ovaries can endanger the overall supply of oocytes, and could lead to an earlier onset of menopause. In working women, there is a trend to delay having children, so if the ovaries are damaged by COVID-19 vaccine injury, there could possibly be a much shorter window in which they will be able to conceive. While this is a hypothetical risk, it is serious enough to warrant caution when weighing the risks and the benefits of the COVID-19 genetic vaccines.

- **Transfer of COVID-19 Vaccines into Breast Milk Following Vaccination of Lactating Mothers**

36. A small scale study of 11 lactating women by Hanna *et al.* (2022) found after inoculation with either the Pfizer/BioNTech or Moderna RNA COVID-19 vaccines that trace levels of the Spike RNA were detectable in the breast milk of 5 of the participants in the first 45 hours post-administration.[55] In other studies, 2 of 9 breast milk samples in one study (collected 1 to. 3

[55] Hanna, N., Heffes-Doon, A., Lin, X., De Mejia, C.D., Botros, B., *et al.* (2022) Detection of messenger RNA COVID-19 vaccines in human breast milk. JAMA Pediatr. 176(12):1268-1270. doi:10.1001/jamapediatrics.2022.3581

days after first vaccination),[56] and breast milk samples from 4 of 31 mothers in another study,[57] also confirmed the transfer of Spike RNA from the vaccine into milk. In the later study,[57] a total of 10/16 and 10/25 mothers had detectable vaccine RNA in their serum 1-3 days of their first vaccination and 7-10 days, respectively, after their second dose of the COVID-19 RNA vaccine. However, the presence of the RNA in the serum of their breast-fed infants has not been reported.

37. These studies confirm Dr. Bridle's claim that COVID-19 mRNA vaccines are able to transfer into breast milk following vaccination of lactating mothers.

38. With respect to the effects of recent COVID-19 vaccination on breast feeding from lactating women, there are limited studies, for which the work of Kachikis *et al.* (2022), among the most representative.[58] Some of the possible adverse effects reported included: 355 of 10,278 (3.5%) lactating women reported a decrease in breast milk supply. Further, all signs and symptoms were recorded during the first 24 hours post-vaccination and from a given list of options. When asked about other signs symptoms post-vaccination, the participants were instructed to record them only if they thought they were related to vaccination, which makes the data collection subjective to the participants' own biases.

[58] Kachikis, A., Englund, J.A., Covelli, I., Frank, Y., Haghighi, C., *et al.* (2022) Analysis of vaccine reactions after COVID-19 vaccine booster doses among pregnant and lactating individuals. JAMA Netw Open. 5(9):e2230495. doi:10.1001/jamanetworkopen.2022.30495

39. In a Pfizer post-marketing report,[59] the authors considered 133 reports of the vaccinated mother breast feeding. Of these, 116 were taken to be normal; of the 17 cases with adverse events listed, 3 were considered "serious" and 14 "non-serious." The symptoms in the infants included: pyrexia (fever), rash, irritability, vomiting, diarrhea, insomnia, poor feeding, lethargy, abdominal discomfort, allergy to vaccine, increased appetite, anxiety, crying, poor sleep quality, eructation (belching), agitation, pain and uticaria (hives).

40. Fu *et al.* (2022)[60] conducted a meta-analysis of 23 studies that examined the immune response in pregnant and lactating individuals to COVID-19 vaccination. They noted that these individuals experienced vaccine-related reactions at a similar rate to the general population. With respect to whether the levels of IgA anti-Spike in breast milk was higher following vaccination against COVID-19 or if it was higher in lactating individuals that had previously been infected with SARS-CoV-2, the authors noted that the findings in the literature were conflicting.

- **Canadian Blood Services uses Blood from Recently COVID-19 Vaccinated Individuals**

41. Dr. Bridle noted in his interview with Alex Pierson that the Canadian Blood Services uses blood from recently vaccinated individuals for transfusions. This is true. As stated on the Canadian Blood Services website,[61] "*Consistent with our eligibility criteria for other non-live*

[61] (2023) COVD-19 vaccines and blood donation. Canadian Blood Services. Retrieved from https://www.blood.ca/en/covid19/vaccines-and-blood-donation.

vaccines, Canadian Blood Services accepts donations from otherwise eligible donors who have received a Health Canada-authorized COVID-19 vaccine, with no required deferral period following vaccination." It is further stated, "*Canadian Blood Services does not reflect vaccination status for any COVID-19 or other vaccines on the labels of products derived from blood donations."*

42. I do not think that the transfer of blood from a COVID-19 vaccinated person to a non-vaccinated individual is likely to cause significant injury, except in one particular scenario. In a person that has been recently vaccinated, the vaccine lipid nanoparticles are likely quickly taken up by the cells of the body, so there should be relatively low concentrations of the free vaccine lipid nanoparticles in the sampled blood. Moreover, during the temporary storage of the blood, the erythrocytes are likely to take up any of the remaining lipid nanoparticles. However, in the first few weeks after COVID-19 vaccination, especially with the second and subsequently doses, there will be high titres of anti-Spike antibodies. If the individual that receives the blood sample receives a COVID-19 vaccination within a few days prior to the transfusion, then there is a high prospect that the anti-Spike antibodies from the donor blood sample will induce a strong inflammatory reaction against the cells in the recipient that took up the lipid nanoparticles. Since the health of the blood recipient may already be compromised, and especially if the SARS-CoV-2 virus is in the environment and the risk of exposure is high, the distraction of the innate immune system to fight what is perceived as an active SARS-CoV-2 infection in the rest of the body could result in an easier infection of the upper respiratory system. Most of the response of intramuscular injection of COVID-19 vaccines is production of the IgG class of antibodies, which are in much lower concentrations in the nasopharyngeal passages and upper lungs, where mucosal antibodies of the IgM and

IgA classes predominate. Ironically, the COVID-19 vaccination of the blood recipient would increase the prospect that they will be infected by SARS-CoV-2 with the possibility of more severe and contagious COVID-19.

- **Concentration of COVID-19 mRNA vaccine lipid nanoparticles in Ovaries and Risk of Infertility**

43. As pointed out in paragraph 15, from biodistribution studies carried out in rats, the lipid nanoparticles used in the Pfizer/BioNTech COVID-19 vaccine (which are very similar to those used in the Moderna COVID-19 vaccine) are known to concentrate in ovaries within 48 hours.10 12 At the last time point in the biodistribution studies, only 24.6% of the lipid nanoparticles were still at the site of injection, and the ovaries were the fourth major site with an uptake of about 0.1% of the total lipid nanoparticles injected. However, due to the small size of the ovaries, the concentration of lipid nanoparticle was high at 10 micrograms of lipid equivalent per gram of tissue) The concentrations of the other major organs that accumulated the lipid nanoparticles were liver at 24.3, spleen at 23.4, adrenal glands at 18.2, and bone marrow at 3.77 μg/g.[10]

44. As noted in paragraphs 27-34, the COVID-19 RNA vaccines affect menstrual cycles in many women following their inoculation, and this is normally controlled by hormones produced by the hypothalamus and pituitary gland in the brain and the ovaries. It is also noteworthy that the COVID-19 RNA vaccine have also been correlated with a temporary reduction in sperm

counts and motility in males.[62] [63] [64] However, other studies were unable to detect COVID-19 RNA vaccine induced reduction of sperm counts or motility.[65] Unlike continuous new sperm production in males through to old age, in females, all of the oocytes that will ever be produced are already present at the time of birth as described in paragraph 36. Therefore, an inflammatory attack by immune cells against the Spike protein expressed in ovarian cells could result in damage to the ovaries and the oocytes stored therein. This is similar to the mechanism that is proposed to underlie COVID-19-vaccine induced myocarditis.[28] [66] [67]

45. The question is whether there has been indeed a reduction in female fertility rates in Canada since the introduction of the COVID-19 vaccines. From 2019 to 2020, the Canadian fertility rate declined by 4.1% from 1.47 children per woman in 2019 to 1.41.[68] In 2021, it slightly increased by 2.1% to 1.44 children per woman, but then dropped by 7.6% to 1.33 in 2022.[69] The highest decline in birthrate was in women 20 to 24 years with a 37.5% decline, followed by 34% in 15- to 19-year-olds, 17% in 25- to 29-year-olds, then dropping to 7.6% in 30- to

34-year-olds, and leveling off after that for 35- to 49-year-olds.[70] From 2019 to 2022 in Canada, the crude birth rate decline was 8.6%; total fertility rate decline was 12%.

46. Worldwide, the steady decline during the pandemic period of 2019 to 2023 in fertility continued, but includes both countries with high mRNA vaccine uptake, as well as those with very low rates. It should be appreciated that birthrates have declined yearly by approximately 4% per annum since the 1950s in most nations.[71]

47. The reduction in birthrates from the beginning of the COVID-19 pandemic, to the later introduction of mRNA and other COVID-19 vaccines may be due to a number of possibilities such as: the influence of COVID-19 or the COVID-19 genetic vaccines on lowered birthrates, the overall decline in male sperm levels, increased economic hardship and social impacts of the pandemic, as well as concerns about having children given the current world situation. In Canada, conscious decisions not to have children during the current uncertain period and the lack of available housing in addition to these other factors, have contributed to the lower birth rate during the COVID-19 crisis.[72] Thus, while it may be tempting to attribute the decline in birthrates at least in part to COVID-19 vaccines, it is premature to make this a solid conclusion. **However, Dr. Bridle was right, and professionally diligent, when he posited the query, in his interview, of whether we should look deeper into this potential issue.**

Section D. Dr. Fisman Qualifications to Opine on Dr. Bridle's Expertise

48. In Dr. Fisman's affidavit, he identified himself as a physician that specializes in infectious disease and as a professor of epidemiology at the Dala Lana School of Public Health at the University of Toronto. From his Wikipedia profile,[73] he completed his M.D. at University of Western Ontario and obtained a Masters of Public Health at Harvard School of Public Health. He did his internal medicine residency training at McGill University and Brown University. He did further training at Beth Israel Deaconess Medical Center and Harvard School of Public Health.

49. From my reading through the titles of 260 publications available on PubMed that Dr. Fisman is listed as a sole or coauthor, and reading through a large sampling of these publications, it is evident that his work focuses on mathematical modeling of primarily infectious diseases and meta-analysis of data from other scientific reports. What is apparent from his training and written works is a lack of depth when it comes to the molecular and cellular mechanisms of immunology, microbiology, virology and vaccinology, which are the domains in which Dr. Bridle researches and publishes.

50. In his criticisms of Dr. Bridle's claims, Dr. Fisman has relied primarily on "fact checkers" who have limited expertise on their own to evaluate their validity.[22] [23] In my reading these articles, selected experts are usually quoted with little critical review of the published work that supports their opinions. While science can be controversial by nature, this is usually exercised by civil debate backed up by peer-reviewed evidence that can be critically analyzed. Someone who is truly an expert in their field would have little trouble finding primary references in the scientific literature rather than turn to websites where journalists write

[73] (2023) David Fisman. Wikipedia. Retrieved from https://en.wikipedia.org/wiki/David_Fisman

opinion pieces that generally push a particular narrative. While Dr. Fisman offers a limited number of scientific publications that support his viewpoint, these are few and far in his affidavit and in some cases are questionable in their own right. For example, Dr. Fisman cites the mathematical modeling study of Davies *et al.* (2021) as supportive of his opinion that early adoption of COVID-19 vaccination could have permitted herd immunity and saved lives from this disease.[74] However, such mathematic models are only as good as the assumptions used to drive such approximations. For example, the Davies *et al.* (2021) publication, it is assumed that COVID-19 vaccination reduced the occurrence of COVID-19 disease by 95%, which was based on relative risk reduction rather than absolute risk reduction, waning efficacy of the vaccines was not accounted for, and it seems to be assumed that those that were vaccinated and got COVID-19 would not be particularly transmissible for the SARS-CoV-2 virus. As I will explain later, these are some of the same pitfalls that Dr. Fisman has made in his own modelling of the impacts of COVID-19 vaccination on the outcomes of the COVID-19 pandemic in Canada.

51. I would also point out that other modeling groups in the UK, such as led by Dr. Neil Ferguson at the Imperial College London, projected COVID-19 deaths that were out by more than an order of magnitude.[75] Dr. Ferguson's models recklessly projected exaggerated COVID-19 deaths during the February to May 4, 2020, period in the absence of lockdowns and his prescribed non-pharmaceutical interventions to be in the range of 400,000 to 610,000 in the

[74] Davies, N.G., Abbott, S., Barnard, R.C., Jarvis, C.I., Kucharski, A.J., *et al.* (2021) Estimated transmissibility and impact of SARS-CoV-2 lineage B.1.1.7 in England. Science. 372(6538):eabg3055. doi:10.1126/science.abg3055

[75] Magness, P.W. (2021) The failure of Imperial College modeling is far worse than we knew. American Insitute for Economic Research. Retrieved from https://www.aier.org/article/the-failure-of-imperial-college-modeling-is-far-worse-than-we-knew/

UK, when the actual number of deaths was 28,734.[76] For almost all of the first year of the COVID-19 pandemic, there were no COVID-19 vaccines for the public. Dr. Ferguson and his colleagues forecasted 7 billion SARS-CoV-2 infections and around 40 million deaths world-wide by the end of 2020 if drastic measures were not implemented and the virus was left unchecked. [77] These estimates of morbidity were wildly over-estimated. As of October 15, 2023, over 3 and a half years into the COVID-19 pandemic, there has been some 771 million confirmed COVID-19 cases, although the actual number of SARS-CoV-2 infections is probably closer to 7 billion, and the cumulative deaths with COVID-19 were reported to be just under 7 million.[78] While the serological prevalence of SARS-CoV-2 infections in Canada[79] and in many other countries around the world is over 80%, the death toll has been vastly smaller than predicted by the Fergusson model. Unfortunately, such estimates were initially treated as near-factual representations and used to guide public policy in the UK and abroad.

52. Unfortunately, Dr. Fisman seems to be Canada's counterpart to Dr. Ferguson as a purveyor of doom and gloom with projected COVID-19 casualties without enforcement of strict public health measures and mandates. His own flawed COVID-19 pandemic modeling was reported in the Canadian Medical Association Journal article entitled "Impact of population mixing

between vaccinated and unvaccinated subpopulations on infectious disease dynamics: implications for SARS-CoV-2 transmission."[80] The publication promoted the concept that the spread of SARS-CoV-2 was primarily from the unvaccinated to the COVID-19 vaccinated, which was widely disseminated in the popular press. This article also received widespread critical commentary, including many calls for retraction of the article directly to the journal, which is the way that academics normally criticize each other works. [81] [82] [83] A whole book has been written about the problems associated with Dr. Fisman's work.[84]

53. Some of the major issues with his modeling included:

    a. Using relative risk reduction rather than absolute risk reduction with the COVID-19 vaccines;

    b. Over-inflating the effectiveness of COVID-19 vaccines and ignoring evidence of negative efficacy with booster shots;[85] [86]

c. Falsely assuming that the protection from COVID-19 vaccination did not wane;

d. Falsely assuming that vaccinated people do not get infected, do not get sick, and do not transmit SARS-CoV-2. Real-world data shown on the Ontario Public Health website on March 31, 2022 showed that 70% of hospitalized COVID-19 cases at the time were fully vaccinated for COVID-19.[87] There are no data that support the notion that vaccinated individuals with COVID-19 do not transmit SARS-CoV-2 with viral loads that are different from unvaccinated individuals;

e. Underestimating the percentage of the population that has been infected with SARS-CoV-2 as under 20% even after the Delta and Omicron waves of the virus sweeping through Canada. This should have been more like 80% or higher,[88] and which if used as a parameter instead of 20% would have completely flipped the conclusions of the model, *i.e.*, the unvaccinated were protecting the vaccinated from spread of COVID-19;

f. Almost completely ignoring the protection conferred by natural immunity;

g. Ignoring any safety issues related to COVID-19 vaccination such as for example, thrombosis, Gullian-Barré syndrome, myocarditis and myopericarditis; and

h. It does not help that Dr. Fisman was highly conflicted as a consultant on advisory boards related to influenza and SARS-CoV-2 vaccines for Pfizer, AstraZeneca, Seqirus and Sanofi-Pasteur.

---

54. Prior to his resignation as an active member of its modeling group, Dr. Fisman also played a key role in the Ontario Science Table, which prominently advised the Ontario provincial government on policy during COVID-19 pandemic.[89] In the end, even Dr. Fisman *et al.* (2022) stated that "*the simplicity of our model is …. a weakness, because it does not precisely simulate a real-world pandemic process in all its complexity.*" [80] So while they concluded, "*we found that the choices made by people who forgo vaccination contribute disproportionately to risk among those who do get vaccinated*," this is clearly conjecture since no real-world observations with people were used to test their study. Thus, although the title of the publication implied that there was actual mixing of populations in the study, this did not actually transpire.

55. Regretfully, Dr. Fisman's dubious COVID-19 pandemic modeling is not unique in Canada. Modeling performed by the Public Health Agency of Canada (PHAC) has also been roundly criticized for being overly simplistic, relying on outdated assumptions and flawed reasoning.[90] Secrecy should have no place in this context. If models are used to guide society's actions and potentially impose risks, complete transparency is essential, and the entire model must be subject to critical discussion. Unlike his earlier modeling work, including with the Ontario Science Table, at least Dr. Fisman made his more recent COVID-19 pandemic modeling more open to analysis, which exposed many of its problems as outlined above.[80]

---

56. Modeling, like science, is an iterative process that thrives on evaluation and correction. An authoritarian approach to science is inherently flawed. Throughout the pandemic, numerous examples emerged where insightful individuals from disparate fields, such as or physics and geology, identified problems within the domain of epidemiology missed by others.[91] [92] Ethical considerations aside, allowing open discourse is the only way to prevent echo chambers from leading society into catastrophic scenarios. For this, transparency is indispensable.

57. Academic freedom as a university professor affords the opportunity for Dr. Fisman to express his opinions in a scholarly manner on matters in which he had demonstrated expertise. However, it is unfitting for a professor of his stature to make public statements about another biomedical research scientist in a different discipline when he does not appear to have the requisite specialized knowledge to claim in his affidavit that Dr. Bridle's interpretations, analyses and opinions are:

    a. "contrary to the overwhelming majority of scientific opinion" (para. 13)
    b. "have the potential to harm or halt Ontario's vaccine rollout" (para.15)
    c. "spreading misinformation regarding COVID-19 vaccines" (para. 20)
    d. "misinformation on the efficacy of vaccines" (para. 28)
    e. "Dr. Bridle's claims are implausible and not data based" (para.30)
    f. Dr. Bridle's information is "not scientifically sound" (para. 41)

[91] Rancourt, D.G., Baudin, M., Mercier, J. (2021) Analysis of all-cause mortality by week in Canada 2010-2021, by province, age and sex: There was no COVID-19 pandemic, and there is strong evidence of response-caused deaths in the most elderly and in young males. ResearchGate. doi: 10.13140/RG.2.2.14929.45921

[92] Ruechel, J. (2021) Autopsy of a pandemic: The lies, the gamble, and the Covid-zero con. Independently published

g. "Dr. Bridle's speaking engagements, interviews and articles posed a risk to the public" (para. 42).

58. On the one hand, as I have explained earlier on in paragraphs 15 to 48, there is strong support in the scientific literature to support Dr. Bridle's statements and concerns. It is therefore not in the public interest to not have scientists with highly specialized expertise and their expert opinions labelled as "misinformation." On the other hand, I think the published modeling work on the COVID-19 pandemic by Dr. Fisman, who suggested that the unvaccinated were driving the COVID-19 pandemic in the vaccinated, does qualify as "misinformation" as exemplified in paragraph 53 to 55 above.

Section E. The Changing Response of Public Health Authorities Abroad to COVID-19 Vaccination

59. While most Canadian public health authorities still remain gung-ho about the COVID-19 vaccines, public health authorities in Quebec[93] and many other countries are much less enthusiastic. In fact, the COVID-19 adenovirus vaccines and Medicago, while initially approved by Health Canada, have all since been discontinued in 2023.

61. In view of the mounting and disturbing data about the limited efficacy and serious safety issues associated with the COVID-19 genetic vaccines, health regulatory agencies around the world have begun one after another to discourage or ban the use of these vaccines, especially in younger people. Denmark was the first nation in Europe to invoke this step by stopping

[93] Rigs, A. (2023) COVID-19: Quebec drops recommendation that all should get booster vaccine. Montreal Gazette. Retrieved from https://montrealgazette.com/news/local-news/quebec-covid-vaccine-recommendation-hybrid-immunity

vaccination invitations on May 14, 2022.[94] By autumn 2022, Denmark recommended vaccination only to those over 50 years old and some vulnerable populations.[95]

62. Many other European countries, as well as Australia and some US states such as Florida, have stopped recommending vaccinations for COVID-19 to anyone under 40, 50 or 60 years of age and especially children. Even in 2021, France and Scandinavian countries did not recommend the Moderna vaccine for people under 30 years of age.[96] [97] The United Kingdom Joint Committee on Vaccination and Immunisation (JCVI) no longer recommends vaccination of healthy individuals under 50 years of age in the UK except for those in clinical risk groups or those attending to such individuals.[98] The Federal Office of Public Health in Switzerland also no longer recommends COVID-19 vaccination for healthy people in all age groups, and will not pay for COVID-19 vaccination for anyone, unless medically indicated by a physician for an individual patient with a clear risk-benefit analysis.[99] The Australian government has advised that a booster dose is **not recommended** as of February 2023 for children and

adolescents up to 18 years who do not have any risk factors for severe COVID-19, and only for those 18-64 years of age who have undergone a risk-benefit analysis with their healthcare provider.[100] The German Federation of Hospitals (DKG) called for the mandatory vaccination obligation of healthcare personnel to be revoked after the German Ministry of Health admitted that 1 in 5,000 COVID-19 vaccination shots led to serious side-effects.[101]

63. In April 2023, the European Medicine Agency and the European Parliament finally recognized that at least 11,448 deaths in the EU occurred following COVID-19 vaccination, and that there were 50,648 deaths attributed to these vaccines in the Eudravigilance database as of April 10, 2023.[102] It would appear that health regulatory agencies in Europe and elsewhere have come to realize the clear and present dangers of the COVID-19 genetic vaccines.

64. It seems that the populations of Canada and the US have also finally come to recognize the efficacy and safety issues of the COVID-19 vaccines, despite the heavy messaging from public health officials to the contrary. For example, only about 16% of those 6 months or older in Ontario within the past year had received a COVID-19 vaccination by September 14, 2023.[103] In the US, only about 5.4% of children and 14.8% of adults 18 years and older

received the updated XBB1.5 COVID-19 vaccines by November 17, 2023, whereas 35.1% of children and 36.3% of adults opted to be vaccinated against influenza.[104]

65. It seems to me that Dr. Bridle's voiced concerns regarding the COVID-19 genetic vaccines are being acknowledged by increasing more biomedical researchers and the general public.

Section F. Harms for Alleging Dr. Bridle is "An Immunologist Spreading Misinformation"

66. In reading through Dr. Fisman's affidavit, I noticed that he claimed in paragraph 21 that "*I am not the author or creator of the website byrambridle.com, nor do I play any role in its maintenance*." He further stated "*I directed users to the website as it contains data-based information on COVID-19 vaccine safety concerns*." While Dr. Fisman seems to be ambiguous on whether he actually provided any content or assisted in the creation of content for this website, in any event, he promoted and supported the fraudulent, derogatory, and highly defamatory website by directing traffic to it. As more data continues to emerge about issues with the production, efficacy and safety of the COVID-19 genetic vaccines, Dr. Fisman's own credibility is at jeopardy through his repeated actions that strike me as disingenuous. It is evident from Dr. Fisman's statements in his affidavit that he was well aware that Dr. Bridle was eager to engage him in discussions about the COVID-19 vaccines even privately, and clearly this would have been an excellent opportunity to steer Dr. Bridle straight if he was in error. He was not.

67. It is also clear to me that Dr. Fisman and others have harmed the research and reputation of a highly qualified and otherwise successful expert scientist through their labelling of Dr. Bridle

[104] (2023) Respiratory viruses. Vaccination trends-Adults. Centers for Disease Control and Prevention. Retrieved from https://www.cdc.gov/respiratory-viruses/data-research/dashboard/vaccination-trends-adults.html

as a "spreader of misinformation." Dr. Bridle has not been able to set foot in his own laboratory at the University of Guelph for over two years, and there is no doubt in my mind that his ability to secure research grant funding and attract graduate student and post-doctoral fellow trainees has been compromised. The Canadian biomedical research community is very small and it is easy to tarnish someone's reputation, especially if that person is placed in a position where they are unable to defend their opinions against prevailing dogma.

SWORN BEFORE ME by Steven Pelech in the City of Richmond, in the Province of British Columbia, on this 1st day of December, 2023, in accordance with O. Reg. 431/20 Administering Oath or Declaration Remotely

A Commissioner for Taking Oaths
Rocco Galati B.A., LL.B., LL.M.

Dr. Steven Pelech

This is Exhibit "A" to the Affidavit of Steven Pelech, sworn before me on this 1st day of December 2023

A Commissioner for Taking Affidavits

Rocco Galati, , B.A., LL.B., LL.M.

University of British Columbia

Curriculum Vitae for Faculty Members

Date: **May 12, 2023**

Initial: _____

1. SURNAME: Pelech

FIRST NAME: Steven

MIDDLE NAME(S):

2. DEPARTMENT/SCHOOL: Medicine, Div. Neurology

3. FACULTY: Medicine

JOINT APPOINTMENTS:

4. PRESENT RANK: Professor **SINCE:** Jul 1, 1998

5. POST-SECONDARY EDUCATION

(a)

University or Institution	Degree	Subject Area	Dates
University of British Columbia	B.Sc.	Biochemistry	1975-1979
University of British Columbia	Ph.D.	Biochemistry	1979-1982

(b) Title of Dissertation and Name of Supervisor

Regulation of Phosphatidylcholine Biosynthesis - with Dr. Dennis E. Vance

(c) Continuing Education or Training

(d) Continuing Medical Education

(e) Professional Qualifications

1 Biomedical Research Scientist

6. EMPLOYMENT RECORD

Prior

University, Company or Organization	Rank or title	Dates
University of British Columbia	Assistant Professor	July 1, 1988 - June 30, 1993
University of British Columbia	Associate Professor	July 1, 1993 - June 30, 1997
University of British Columbia	Postdoctoral Fellow (with Dr. Dennis Vance)	1983-1983
University of Dundee, Scotland	Postdoctoral Fellow (with Dr. Philip Cohen, knighted as Sir Philip Cohen)	1983-1984
University of Washington, Seattle	Postdoctoral Fellow (with Dr. Edwin Krebs, Nobel Prize recipient)	1984-1987
Biomedical Research Centre, Vancouver (Immunology Institute)	Senior Scientist	1987-1998
Kinetek Pharmaceuticals, Inc.	Founder, President & Chief Executive Officer	1992-1997

Present

University, Company or Organization	Rank or title	Dates
University of British Columbia	Professor	July 1, 1997 - present
Kinexus Bioinformatics Corporation	Founder, President & Chief Scientific Officer, Director	1999-present

c) Date of granting tenure at UBC:

July 1, 1993

7. LEAVES OF ABSENCE

University, Company Or Organization at which Leave was taken	Type of Leave	Dates

None taken since starting as a UBC faculty member. However, from November 3, 2004 through to April 15, 2005, I was summoned for 24 full days to appear in a B.C. Human Rights Hearing Case. I also had to appear in the BC Supreme Court for a judicial review of this case over a week's period in April 2009.

8. TEACHING

(a) Areas of special interest and accomplishments

1 Percentage of Overall Time Devoted to:

Non-clinical instruction:	20%
Clinical instruction:	0%
Research/publication:	55% (includes R&D at private biotechnology company)
Administration (UBC):	20%
Administration (Kinexus):	5%
Clinical practice:	0%

---

2 For over 30 years, I was very active in the establishment of the Experimental Medicine Graduate Program and have worked closely with its six directors (i.e. Drs. Rabkin, Quamme, Wong, Duronio, Sly and Tang). My goal was to develop courses that would provide practical, useful skills to graduate students. In particular, the students should acquire a solid knowledge base, be able to read the scientific literature and on-line websites critically, adapt to new lab environments and assimilate new techniques, deliver clear oral presentations, and write competitive grants for funding.

3 To improve the knowledge-base of Experimental Medicine students, I became the course coordinator for MEDI 501, a lecture course that is required of all students in the program and focuses on the molecular basis of disease. I originally presented the opening four lectures for this course, which is taught by several faculty members. I am convinced that future improvements in the treatment of diseases will depend upon a firm understanding of the molecular mechanisms underlying the diseases. Imparting this knowledge to graduate students will better prepare them for disease-related research. In 2022, I taught one 90 minutes lecture each term. I also provide an examination question for the mid-term exam and graded 19 answers.

4 To improve the laboratory skills of Experimental Medicine students, I became the course coordinator for MEDI 502, which is the second course that is required of all students in the program. Previously, the students went on mass together to a different lab each week to see a technique taught by a faculty member. I altered the course so that each student could select two host labs out of two dozen possible labs in which they would spend half a day per week for two months in each lab learning about the research area and various techniques in use in that lab. This improved research interactions among various members of the Department of Medicine. Half way through this course, the student has to give to the other students in the course a 20 minutes

oral presentation that outines the nature of the research in the first host lab and a technique that is being used to approach a biological problem in that lab. At the conclusion of the rotation in the second host lab, the student has to write an MRC grant application that combines aspects of his experience in the host laboratories. The oral presentation and the grant application account for the majority of the final grade for this course. This is the only course of this kind that is offered through the U.B.C. Currently, I take on one to two students per term in my laboratory for this course.

5 I have also provided the opportunity for many undergraduate students to obtain research experience in my laboratory through the BIOL 448A and MEDI 548 Directed Studies courses and the cooperative education programs at the Department of Microbiology and Immunology at U.B.C. and the Simon Fraser University Science Coop. From these coop programs, over 200 undergraduate students have work full-time in my laboratory under my supervision for 4 to 12 month terms.

6 My area of research expertise is signal transduction, and there is growing appreciation that defective cell signalling is at the root of cancer, Alzheimer's, diabetes, immune disfunction and many other chronic diseases of aging. As there was no advanced, graduate level course in signal transduction that was offered each year at U.B.C., I decided to create one. The majority of my teaching is in the MEDI 590 Cell Regulation course, which I coordinate and deliver all of the lectures. The course is very advanced and covers a lot of ground, but most students perform very well. The final mark for MEDI 590 course is now largely dependent upon an exercise to gather detailed information about various members of a family of cell signalling proteins. This exercise forces the students to read the scientific literature and collect data from relevant websites, and present their results organized in Excel tables. The collected information is made available to the scientific community after it is integrated into a database. In 2022, there were 11 registered graduate students that initially took the course as well as one Ph.D. student that audited the course. All of the 56 hours of PowerPoint lectures and supporting materials are provided to all the students in pdf format in advance of each class. I devoted over 30 hours additional outside of the classroom in 2022 in MEDI 590 course preparation, including the development of new original content and marking midterms and final assignments. I have made much of these educational materials available to wider audiences on the Kinexus Bioinformatics website at www.kinexus.ca. My long term objective is to produce 10 minute teaching videos of portions of the lectures for the MEDI590 course that will be posted on-line with open-access.

7 Another course that I originally coordinated for five years is MEDI 535, which I designed to be a journal club in which the participants critically analyze recent scientific papers based on signal transduction research. In this course, the students received a scientific paper a week before the next class that they are expected to read and critically review. The following week, the student that originally selected the paper provided a brief synopsis of the paper and then led the round table discussion among myself and the other students of the paper's strengths and deficiencies. I believe that this course provides the students with strong analytical skills that are useful when the students prepare their own scientific manuscripts and for when they read the literature. I have not tutored in this course in recent years.

8 I have also provided 2 hours of lecture per year in the Neuroscience 500 course (1999-2001), I participated as a medical student PBL tutor in the Endocrinology Block for Second Year (1999, 2000) and Hyperplasia Block for First Year), gave a 1 hour lecture to First Year Medical Students (2002) and 2 hours of lecture per year in Pathology 500 (2001, 2002) and 2 hours of lecture to Pharmaceutical Sciences graduate students in PHAR 545 (2003).

(b) Recent Courses Taught at UBC:

Year	Session	Course Number	Scheduled Hours	Class Size	Hours Taught			
					Lecture	Tutorials	Labs	Other
2019 + 2020	Fall 2019 + Winter [illegible]	BIOL 448 – Directed Studies	60	1 – Kevin Wong	0	5	>250 h	1
2019 + 2020	Fall 2019 + Winter [illegible]	ISCI 448 – Directed Studies	60	1 – Abiel Kwok	0	5	>250 h	1
2020	Winter 2020	MEDI 502 - Molecular and Cellular Biology	30	1 – Jackie Ho	0	4	10	1
2020	Fall 2020	MEDI 590 - Molecular Regulation of Cell Growth	>100	9	56	0	0	>100 h (see Note 1)
2020	Fall 2020	MEDI 501 - Molecular and Cellular Biology	7	19	1.5	0	0	+5.5 h (see Note 2)
2021	Fall 2021	MEDI 590 - Molecular Regulation of Cell Growth	>100	4	52	0	0	>50 h (see Note 1)
2021	Fall 2021	MEDI 501 - Molecular and Cellular Biology	10	30	1.5	0	0	+5.5 h (see Note 2)
2022	Fall 2022	MEDI 590 - Molecular Regulation of Cell Growth	>100	6-12	52	0	0	>50 h (see Note 1)
2022	Fall 2022	MEDI 501 - Molecular and Cellular Biology	10	24	1.5	0	0	+5.5 h (see Note 2)

Note 1 - +50-150 h course preparation; +2 h for midterm; +2 h midterm marking; + >50 h final assignment marking

Note 2 - +4.5-10 h lecture preparation and mid-term or final exam marking

(c) Graduate Students directly supervised at UBC:

Student Name	Program Type	Year		Principal Supervisor	Co-Supervisors
		Start	Finish		
Palaty, Chrystal	Exp. Med. Ph.D.	1990	1995	Pelech

21	Jackie Ho	UBC, MEDI 502	January 29 – February 28, 2020

In 2012, I also marked mock grant reviews prepared by Mary Rose Pambid and Saeideh Davoodi as part of the MEDI-502 course.

(e) MBA Student Supervision (at my industrial lab at Kinexus)

1	Deborah Bender	SFU, MBA Student	May 1 - July 31, 2001
2	Darius Panaligan	SFU, MBA Student	June 5 - August 31, 2001

(f) Undergraduate Coop Student Research Supervision (at my industrial lab at Kinexus)

I have taken on over 175 undergraduate students from the Simon Fraser University, University of Victoria and University of B.C. Coop programs through my companies Kinetek Pharmaceuticals Inc. (1992-1998) and Kinexus Bioinformatics Corp. (1999-present). Most of these students worked on average for 8 months full work-terms. I have only listed my trainees at Kinexus below.

No.	Name of Student	Months	Start Date	End Date
1	Korine Ung	4	1-Sep-1999	30-Dec-1999
2	David Brewster	4	1-Jan-2000	30-Apr-2000
3	Michael Hsing	8	1-Jan-2000	31-Aug-2000
4	Pinky Chua	4	1-May-2000	31-Aug-2000
5	Bonnie Jones	8	1-May-2000	31-Dec-2000
6	Claire Hou	4	1-Sep-2000	31-Dec-2000
7	Tiffany Chen	8	2-Jan-2001	31-Aug-2001
8	Christopher Huang	8	2-Jan-2001	31-Aug-2001
9	Kevin Ma	8	1-May-2001	31-Dec-2001
10	Jason Sterne	8	7-May-2001	31-Dec-2001
11	Kristy Lynn Williams	8	27-Aug-2001	31-Dec-2001
12	Jeff Druce	8	27-Aug-2001	31-Dec-2001
13	Mark White	4	27-Aug-2001	31-Dec-2001
14	Jack Min	4	4-Sep-2001	31-Dec-2001
15	Jill Youds	8	1-Jan-2002	31-Aug-2002
16	Jackie To	8	1-Jan-2002	31-Aug-2002
17	Marina Kanjer	4	1-Jan-2002	30-Apr-2002
18	Andrea Ramalho	8	1-Jan-2002	30-Aug-2002
19	Leon Poznanski	8	1-May-2002	31-Dec-2002
20	Devon Yeoman	8	1-May-2002	31-Dec-2002
21	Kyla Hingwing	8	1-Sep-2002	30-Apr-2003
22	Gavin Lee	4	10-Sep-2002	31-Dec-2002
23	Richard Li	8	1-Jan-2003	30-Aug-2003
24	Anna Moorhouse	8	1-Jan-2003	30-Aug-2003
25	Beth Clendening	8	22-Apr-2003	31-Dec-2003
26	Shauna Murray	12	25-Aug-2003	31-Aug-2004
27	Heidi Cheung	8	1-Sep-2003	30-Apr-2004

(g) Undergraduate BC Institute of Technology Student Supervision (at my industrial lab at Kinexus)

I directly worked with each of these students in the development of the open-access, on-line databases and knowledgebases hosted Kinexus Bioinformatics Corporation. These usually involved bi-weekly interactions for 1 to 2 hours over a 5 to 6 week period.

1	Anchal Jain	BCIT Computer Sci. Prgm.	21-June-2005 to 10 –Sep-2005
2	Eric Chua	BCIT Computer Sci. Prgm.	21-June-2005 to 10 –Sep-2005
3	Ho Sand (Alex) Lee	BCIT Computer Sci. Prgm.	21-June-2005 to 10 –Sep-2005
4	Jimmy Chan	BCIT Computer Sci. Prgm.	12-Oct-2005 to 25 –Nov-2005

29	Keegan Kelly	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011

30	Aly Jamani	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
31	Colin Nguyen	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
32	David Gannon	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
33	Lili Hao	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
34	Mila Khadarina	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
35	Andrii Skrynnyk	BCIT Computer Sci. Prgm.	26-Apr-2011 to 27-May-2011
36	Kyle Li	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
37	Theo Mutia	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
38	Travis Ryder	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
39	Clarence Sng	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
40	James Chen	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
41	Andy Chow	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
42	Sunju Christine Jeong	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
43	Dan Stephenson	BCIT Computer Sci. Prgm.	21-Apr-2013 to 24-May-2013
44	Nadezhda Dobrianskaia	BCIT Computer Sci. Prgm.	20-Apr-2015 to 18-May-2015
45	Guanyi Fang	BCIT Computer Sci. Prgm.	20-Apr-2015 to 18-May-2015
46	Calvin Truong	BCIT Computer Sci. Prgm.	20-Apr-2015 to 18-May-2015
47	Kevin Thet	BCIT Computer Sci. Prgm.	20-Apr-2015 to 18-May-2015
48	Haruna Kakinoki	BCIT Computer Sci. Prgm.	20-Apr-2018 to 18-May-2018
49	Matthew Lau	BCIT Computer Sci. Prgm.	20-Apr-2018 to 18-May-2018
50	Noah McMurchy	BCIT Computer Sci. Prgm.	20-Apr-2018 to 18-May-2018
51	Roberg Koeing	BCIT Computer Sci. Prgm.	20-Apr-2018 to 18-May-2018
52	Ryan Liang	BCIT Computer Sci. Prgm.	10-Sept-2018 to 30-Nov-2018
53	Garth Nelson	BCIT Computer Sci. Prgm.	10-Sept-2019 to 30-Nov-2018
54	Andy Tang	BCIT Computer Sci. Prgm.	10-Sept-2018 to 30-Nov-2018
55	Thomas Bui	BCIT Computer Sci. Prgm.	10-Sept-2019 to 25-May-2020
56	Saeed Naguib	BCIT Computer Sci. Prgm.	10-Sept-2019 to 25-May-2020
57	Daria Dimchuk	BCIT Computer Sci. Prgm.	10-Sept-2019 to 25-May-2020
58	Dawson Verboven	BCIT Computer Sci. Prgm.	10-Sept-2019 to 25-May-2020

I have also provided co-supervision for UBC Computer Science Ph.D. candidate Mr. Alireza Davoodi with Dr. Jan Manuch in a MITAC Project from April 1, 2013 for the KinATLAS website.

(h) Continuing Education Activities

1 February 9, 2005 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

2 November 9, 2005 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

3 November 30, 2005 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

4 February 15, 2006 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

5 March 15, 2006 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and

Tenure

6 November 8, 2006 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

7 April 11, 2007 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

8 November 14, 2007 – UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

9 November 21, 2007 - UBC TAG Workshop for Dept. of Urology – Preparation of Teaching Dossier for Promotion and Tenure

10 March 5, 2008 - UBC TAG Workshop – Preparation of Teaching Dossier for Promotion and Tenure

11 January 26, 2022 - UBC Ethics in the Arts Workshop

12 July 20, August 31, October 26 - UBC Racism Workshop - Decolonial and Anti-Racist Approaches to Wellbeing with Future Ancestors' Larissa Crawford

(i) Visiting Lecturer (indicate university/organization and dates)

This is included with my invited presentation list in Section 9(d).

(j) Mentor for Sabbatical

1	Dr. Byung Soon Moon – Professor and Head of Surgery, WONKWANG University Iksan Oriental Medical Center, Korea, February 1, 2007 - January 31, 2008

(k) Other

1 MRC Representative for Scholarships Day at U.B.C. - October 25, 1991; Sept. 24, 1992

2 Volunteer for Careers Presentation - Science World, Vancouver - March 9, 1993

3 Scientists & Innovators in the Schools, Kitsilano Secondary School, Vancouver -Feb. 14, 1993

4 Volunteer for Careers Presentation - Science World, Vancouver - March 1, 1996

5 Scientists & Innovators in the Schools, Gladstone Secondary School, Vancouver -January 24, 1997

6 Volunteer for B.C. Regional Science Fair, University of B.C. - April 5, 2001

High School Student Mentorship (1 day to 2 weeks) at my industrial lab at Kinexus

1 Davita Fuchs - Windermere Secondary School, Vancouver, 24-29-Jul-2001

2 Ariella Zbar – Eric Hamber High School, Vancouver, 26-30-Aug-2002

3 Tom Chan - Windermere Secondary School, Vancouver, 27-31-Jan-2003

4 Nga Wailau - Windermere Secondary School, Vancouver, 23-27-Jun-2003

5 Maggie Lau - Windermere Secondary School, Vancouver, 21-25-Jul-2003

6 Winnie Chen – Prince of Wales Secondary School, Vancouver, 18-22-Aug-2003

7 Peter Quon - Windermere Secondary School, Vancouver, 26-30-Jan-2004

8 Reginald Naidu - Windermere Secondary School, Vancouver, 17-30-Jun-2004
9 Anthony Leung - Windermere Secondary School, Vancouver, 24-28-Jan-2005
10 Ricky Quan - Windermere Secondary School, Vancouver, 20-25-Jun-2005
11 Dorothy Yeung - Windermere Secondary School, Vancouver, 23-27-Jan-2006
12 Sophia Guerrero - Windermere Secondary School, Vancouver, 19 – 30-Jun-2006
13 Alex Sutter- McMath Secondary School, Richmond, 26-30-Jun-2006
14 Yin Woo - Windermere Secondary School, Vancouver, 14-31-Dec-2007
15 Gail Ng - Windermere Secondary School, Vancouver, 26-30-Jan-2009
16 Fiona Leung - Windermere Secondary School, Vancouver, 25-29-Jan-2010
17 Leanne Huang - Windermere Secondary School, Vancouver, 21-Jun - 2-Jul-2010
18 Wilkin Chou - Windermere Secondary School, Vancouver, 21-Jun - 2-Jul-2010
19 Rebecca Hu – Templeton Secondary School, Vancouver, 24-25-Jun-2010
20 Angela Pinto – Windermere Secondary School, Vancouver, 22-Jun - 30-Jun-2011
21 Katie Piper – Windermere Secondary School, Vancouver, 22-Jun - 30-Jun-2011
22 Hailey Xi - Secondary School, Vancouver, 16-Dec-2022

(l) Post-doctoral Fellows

1 Dr. Hong Zhang – 2000-2002
2 Dr. Y. J. Xu – 1998-1999
3 Dr. D. F. Liao – 1998 (3 months)
4 Dr. Ian Melhado – 1998 (6 months)
5 Dr. Sanjay Bhanot – 1995-1997
6 Dr. Baljinder Sahl – 1994-1998
7 Dr. Diana Lefebvre – 1994-1996
8 Dr. Brook Koide – 1993-1995
9 Dr. Yaw Loon Siow – 1992-1997
10 Dr. Jasbinder Sanghera – 1989-1995
11 Dr. Maleki Daya-Makin – 1989-1991

9. SCHOLARLY AND PROFESSIONAL ACTIVITIES

(a) Areas of special interest and accomplishments

Role of protein phosphorylation in cellular signal transduction.

1 My research focuses on the characterization of protein-serine kinases involved in mitogen- and stress-signalling and cell cycle control. Protein kinases are major intracellular transducers of information from extracellular stimuli. Their defective signalling, as a consequence of mutations in the genes that encode these enzymes, underlies many degenerative diseases of aging such as cancer, diabetes, immune cell disfunction, heart disease and neurological disorders.

2 The main model systems that are under investigation in my laboratory are oocytes from sea stars and frogs, human solid tumours, insulin-target tissues such as skeletal muscle and heart from normal and diabetic rats, and human brain and spinal cord tissues from patients with neurological disorders. Many of the same protein kinases that are abnormally activated in cancer cells are stimulated in a controlled fashion during the meiotic maturation of oocytes or during activation of terminally differentiated immune cells of the blood, heart and brain.

3 As a postdoctoral fellow in the laboratory of Dr. Edwin Krebs, I was one of the co-discoverers of MAP kinase. Over the last 29 years, my research team and I have shown that MAP kinases such as Erk1 and Erk2 operate in the following mitogen-activated protein kinase cascade: Raf1-Mek-Erk1/2-Rsk1/2. My laboratory examined the role of this protein kinase cascade in platelets, T cells, B cells, macrophages, neutrophils, keratinocytes, cardiomyocytes, oligodendrocytes and neurons. These studies have been expanded for analysis of the related MAP kinase-dependent pathways that involve JNK and p38 MAP kinases.

4 Other protein kinases under scrutiny in my lab include cyclin-dependent kinases, p70 S6 kinase, protein kinase C, oncogene-encoded kinases (e.g. Pim1, Cot and PKB), and a novel protein-histidine kinase. Some of these kinases are activated by second messengers such as calcium, whereas others are regulated by small GTP-binding proteins such as Ras and Rac or via direct phosphorylation by upstream kinases. Anti-peptide antibodies developed in my laboratory have been produced for the specific detection of all of these kinases. Recombinant forms of mammalian versions of kinases are expressed in E. coli, COS cells and baculovirus-infected Sf9 cells. Site-directed mutagenesis is used to identify important regulatory phosphorylation sites in Erk1, Mek1, Mekk and Pim1. Synthetic peptide substrates are used to identify the critical amino acid residues that are required for kinase recognition. Specific roles for these kinases are being defined by identification of their target substrates and by establishing how the kinases are integrated into signaling networks.

5 Other technologies that are applied in my research program include antibody microarrays, multi-immunoblotting, protein sequencing, cDNA cloning, sequencing and site-directed mutagenesis, cell culture and microinjection, and immunocytochemical localization. We can now track over 600 protein kinases, phosphatases, stress, cell cycle and apoptosis proteins in addition to over 900 phosphorylation sites in many of these phosphoproteins. This technology has led to the spin-out of Kinexus Bioinformatics Corporation from my UBC lab.

6 Over the last 20 and a half years, in collaboration with my company Kinexus, I have built a strong bioinformatics program to create databases and knowledgebases that are available online with free

access for the scientific community. KiNET (http://www.kinet.ca) has the results from the analysis of over 10,000 multi-immunoblots performed in-house at Kinexus using the Kinetworks methodology that was development in my UBC lab. It is the largest repository of quantitative proteomics data on cell signalling proteins available. In 2010, we launched the PhosphoNET knowledgebase (www.phosphoNET.ca). It presently has detailed information on over 180,000 experimentally confirmed and 780,000 predicted human phosphorylation sites. PhosphoNET also provides evolutionary analysis and kinase prediction for all 967,000 phosphosites. In 2011, we launched the TranscriptoNET knowledgebase (www.transcriptonet.ca) with detailed mRNA expression data information on 21,000 genes in over 600 different human tissues, tumour types and cancer cell lines. We also released the KiNET-AM database (www.kinet-am.ca) which contains antibody microarray data on 650-800 proteins and phosphosites levels tracked in over 2000 cell and tissues lysates from diverse experimental model systems. In 2013, we launched the DrugKiNET knowledgebase (www.drugkinet.ca) with information on the sensitivities of over 400 protein kinases to more than 850 drugs and other kinase inhibitory compounds. In 2015, we produced beta-versions of the OncoNET knowledgebase (www.onconet.ca) with detailed information on over 3000 proteins related to cancer, and the KinaseNET knowledgebase (www.kinasenet.ca) with detailed information on 536 human protein kinases. Most of these knowledgebases were further updated in 2017 and 2018. In 2018, we also developed a website for drug-protein interactions with identification of the most critical amino acid residues in proteins for the binding of over 2000 approved and experimental drugs (www.drugpronet.ca). I am also working on online knowledgebases for protein phosphatases, adaptor proteins, stress protein and transcription factors. My ultimate goal is to create an atlas of cell signalling maps and the ability to track key proteins and phosphosites within these networks with protein microarrays. Towards this end, I have also been working on producing signalling maps online with Kinections Maps that detail experimentally verified interactions with protein kinases and KinATLAS (www.kinatlas.ca), which features customizable maps of kinase-drug, protein-protein interactions, and kinase-substrate interactions with KiNector (www.kinector.ca).

7 Ultimately, the research undertaken in my laboratory should help identify rational targets for the development of pharmacological agents for the treatment of cancer, neurological diseases, diabetes, autoimmune diseases, and other disorders that involve protein kinases. In addition, it is helping to identify biomarkers that may be useful for diagnosing diseases and defining the most appropriate therapeutic strategies to treat these diseases.

(b)+(c) Research or equivalent grants/contracts (indicate under COMP whether grants were obtained competitively (C) or non-competitively (NC))

Grants

Granting Agency	Subject	COMP	$ Per Year	Year	Principal Investigator	Co-Investigator(s)
Med. Res. Council of Canada	Role of Protein phosphorylation in viral action	C	54,000 -2 yr	1987-1989	Pelech	

B.C. Health Care Res. Foundation	Phosphatidylcholine turnover and protein phosphorylation in lymphokine action	C	12,000 -2 yr	1988-1990	Pelech	
B.C. Health Care Res. Foundation	TL-100 ultracentrifuge - Role of protein phosphorylation in cell cycle progression	C	17,000	1989	Pelech	
Med. Res. Council of Canada	Purification and characterization of cell cycle-regulated protein kinases	C	57,640 -2 yr	1989-1991	Pelech	
B.C. Health Care Res. Foundation	Role of protein phosphorylation in signal transduction by platelet agonists	C	22,000 -1 yr	1990		
B.C. Health Care Res. Foundation	Oocyte microinjection system & microscope	C	19,600	1990	Pelech	
B.C. Health Care Res. Foundation	Role of protein kinase C in signal transduction by platelet agonists	C	23,320 -1 yr	1991	Pelech	
Medical Research Council of Canada	Sorvall RC28S supraspeed centrifuge & F28/36 rotor	C	32,736	1991	Pelech

Can. Inst. Health Res.	Protein kinase pathways in seastar oocyte cell cycle control	C	107,000 - 5 year	2005-2007	Pelech	
Can. Foundation for Innovation	Brain Research Centre: A Platform for Basic and Translational Neuroscience.	C	$6.8 million	2007	Cynader	Pelech + 10 other co-investigators. I wrote approximately 30% of this successful
National Research Council of Canada IRAP	Building the On-line SigNET KnowledgeBank	C	50,000 – 1 year	2009-2010	Pelech	Kinexus Bioinformatics Corporation
Nati. Sci. & Eng. Res. Council of Canada	Mapping the human kineome and phosphoproteome	C	80,000 – 2 years	2009-2011	Stacho + Pelech	Simon Fraser Univ. + Kinexus Bioinformatics Corporation. I wrote 95% of this successful grant

National Research Council of Canada IRAP	Production of Epitope-mapped Phosphosite Antibodies	C	38,000 – 1 year	2011-2011	Pelech	Kinexus Bioinformatics Corporation
National Research Council of Canada IRAP	Development of Protein Kinase/Phosphatase Substrate Microarrays	C	178,000 – 2 years	2012-2014	Pelech	Kinexus Bioinformatics Corporation
National Research Council of Canada IRAP	Development of Protein Kinase/Phosphatase Assays (Salary support for Iqbal Sarai)	C	20,000 – 9 months	2020	Pelech	Kinexus Bioinformatics Corporation
Neurodegenerative Disease Research (NDR), Inc.	Development of Phosphosite Antibodies for ALS Target Proteins	C	US$140,000	2021	Pelech	Kinexus Bioinformatics Corporation
COVID-19 Immunity Task Force	Immmunogenicity of current SARS-CoV-2 vaccine schedules in BC and Ontario	C	$729,149	2021	Pascal Lavoie	Pelech
Neurodegenerative Disease Research (NDR), Inc.	Development of Phosphosite Antibodies for ALS Target Proteins (Salary support for Ghada Maged)	C	US$15,000	2022	Pelech	Kinexus Bioinformatics Corporation

(d) Invited Presentations

83 Local in B.C.; 35 in Canada outside B.C.; 64 in U.S.A.; 36 Internationally, outside of Canada and USA

1 July 1987 - Biochemistry Department, Univ. of B.C.

2 December 1988 - Biochemistry & Molecular Biology, Univ. of Manitoba, Winnipeg, Manitoba.

3 14 December 1989 - Dept. of Obstetrics & Gynaecology, Univ. of B.C., Grace Hospital Site. Regulation of meiotic maturation and egg mitosis by protein phosphorylation.

4 6 February 1989 - Vancouver Council of Woman, Unitarian Church, Vancouver. Present and future of human embryo and fetal research.

5 12 March 1990 - Dept. of Paediatrics, Univ. of B.C., Shaughnessy Hospital Site.

Protein phosphorylation in cell cycle control.

6 21 March 1990 - Pharmacology Department, Univ. of B.C. Cell cycle-regulated protein kinase cascades.

7 July 1990 - Ludwig Cancer Institute, London, U.K.

8 July 1990 - Imperial Cancer Research Fund, London, U.K. Regulation of protein kinase C in haemopoietic cells.

9 July 1990 - Wellcome Biotech., Beckenham, U.K.

10 February 1991 - Biotechnology Building, Cornell University, Itheca, NY, USA. p44mpk - a paradigm for a family of mitogen-regulated, tyrosine-phosphorylated protein-serine kinases implicated in cell cycle control.

11 4 October 1991 - Inst. Molecular Biol. & Biochem., Simon Fraser Univ., Burnaby. MAP kinases, a family of tyrosyl-phosphorylated and activated protein-seryl kinases.

12 8 October 1991 - Dept. of Ophthalmology, Univ. of B.C., Eye Care Centre, V.G.H. MAP kinases, a family of tyrosine-phosphorylated & activated protein-serine kinases.

13 7 November 1991 - Manitoba Inst. of Cell Biology, Univ. of Manitoba, Winnipeg, Manitoba.

14 6 December 1991 - Dept. of Biochemistry, Queens University, Kingston, Ontario. MAP kinases, a family of tyrosyl-phosphorylated and activated protein-seryl kinases.

15 15 January 1992 - Department of Physiology, Univ. of B.C. MAP kinases, God's gift to the Pelech lab.

16 28 February 1992 - Dept. of Microbiology, University of Virginia, Charlottesville, VA, USA. Charting regulatory pathways with MAP kinase.

17 11 March 1992 - Department of Microbiology, Univ. of B.C.

18 9 April 1992 - Department of Anatomy & Cell Biology, University of Kansas, Kansas, USA.

19 8 May 1992 - Department of Biochemistry, University of Calgary, Calgary, AB. Charting regulatory pathways with MAP kinase.

20 17 September 1992 - Div. Endocrinology, Dept. Medicine, Univ. of B.C. Charting regulatory pathways with MAP kinase.

21 11 July 1992 - D. Vance Honourary Symposium, Univ. of B.C.

22 25 October 1992 – Keystone A.S.B.M.B. Symposium, Keystone, CO, USA Chairperson

23 14 November 1992 - Frontiers in Science, Shrum Science Centre, Simon Fraser Univ., Burnaby. The power and promise of biomedical research.

24 3 March 1993 - Dept. of Biochemistry, University of Alberta, Edmonton, AB

25 26 October 1993 - Department of Medicine, Univ. of B.C. Abnormal insulin regulation of protein kinases during diabetes.

26 28 October 1993 - Pharmaceutical Sciences, Univ. of B.C. Insulin-activated protein kinase cascades - A paradigm for mitogenic signalling.

27 4 November 1993 - Department of Obstetrics & Gynaecology, Univ. of B.C. Networking with MAP kinases.

28 8 December 1993 - Department of Biochemistry, McGill Univ., Montreal, QC. Charting regulatory pathways with MAP kinases.

29 18 June 1993 - C.F.B.S. Meeting, Windsor, ON. Merck Frosst Canada Prize Award Lecture for C.S.B.M.B.

30 21 June 1993 - Hotel Dieu Hospital, Montreal, QC. Regulation of insulin-activated protein kinases in diabetic rats.

31 22 June 1993 - N.R.C. Biotechnology Research Institute, Montreal, QC. Networking with protein

kinases.

32 22 September 1993 - European Cell Cycle Conference, La Rochelle, France.

33 1 October 1993 - Biological Regulatory Mechanisms, Rossiter Conference, Barrie, ON. Cell cycle-regulation of serine/threonine kinases

34 18 April 1994 - Dept. Anatomy & Cell Biology, University of Toronto, Toronto, ON. At the cross-roads of diverse signal transduction pathways.

35 April 1994 - Department of Biochemistry, University of Minnosota, St. Paul, MN, USA. Networking with protein kinases.

36 November 1994 - N.R.C. Workshop-Biotechnology Research Institute, Montreal, QC. Signal transduction: Advances and applications.

37 21 May 1994 - Schmitt Symposium: The Cytoskeleton in Alzheimer's Disease, Univ. of Rochester, Rochester, NY. Phosphorylation cascades.

38 14 June 1994 - Dupont Symposium on Biological Signals, C.F.B.S. Meeting, Montreal, QC. Mitogen-activated protein kinases: at the cross-roads of diverse signal transduction pathways.

39 21 June 1994 - XIIth Annual Workshop on Membrane Transport, University of Montreal, Montreal, QC. Protein kinase and phosphatase networks in cell signaling.

40 21 July 1994 - XVI Annual Meeting Internatl. Society Heart Research Symposium, London, ON. Regulation of protein kinase circuitry by growth factors.

41 November 1994 - Onyx Pharmaceuticals, Richmond, CA. U.S.A. MEK'ing connections in MAP kinase-dependent signalling pathways.

42 28 March 1995 - Dept. of Pathology, Univ. of B.C., St. Paul's Hospital. MAP kinase networks in cell proliferation and stress.

43 16 May 1995 - Dept. of Pharmacology, Vanderbilt University, Nashville, TN, USA. Mitogenic and stress-activated protein kinase modules in cellular signalling.

44 29 June 1995 - Internatl. Soc. Neurochemistry Workshop, Nagoya Japan.

45 18 July 1995 - Cornell University, Ithaca, NY, USA.

46 28 August 1995 - Virological and Immunological Mechanisms, Functional Outcomes and Possibilities for Therapy in Enteroviral Heart Disease: An International Workshop, St. Paul's Hospital, Vancouver, Moderator, Ventricular function, myocyte biology, therapeutics.

47 26 January 1995 - Pacific NorthWest Biotechnology Exposition, Westin Hotel, Vancouver.

48 27 January 1995 - Aquatech'95 Conference, Westin Hotel, Vancouver.

49 9 May 1995- John P. Robarts Research Institute, London, ON. MAP kinase pathways in hemopoietic cell activation.

50 15 February 1995 - Merck Frosst - Growth Factor Meeting, Hyatt Regency, Vancouver.

51 11 May 1995 - Weis Centre for Research, Geisinger Clinic, Dansville, PE, USA. Regulation of mitogenic and stress-activated protein kinases.

52 19 May 1995 - ICOS Inc., Bothell, WA, USA.

53 20 July 1995 - W. Alton Jones Science Centre, Lake Placid, NY, USA. Protein kinase circuitry in mitogenic and stress signalling.

54 6 December 1995 - Upstate Biotechnology Inc., Lake Placid, NY, USA.

55 3 May 1996 - Dept. of Surgery, Univ. of B.C., Jack Bell Research Centre. Malfunctions in cell

signaling systems - the molecular basis of chronic diseases.

56 9 May 1996 - Dept. of Pathology, Univ. of B.C., Eye Care Centre. Protein kinases and disease.

57 22 January 1996 - Pierce Chemicals, Rockford, IL, USA.

58 21 February 1996 - Hospital for Sick Children, Toronto, ON.

59 4 March 1996 - Biochemistry, Pharmacology & Physiol. Club of Univ. of B.C.- Keynote Speaker. Your future in the basic medical sciences-bridging academia, government & industry.

60 23 March 1996 - Fisher Winternational Conference, Banff, AB.

61 26 March 1996 - Vancouver Enterprise Forum, Science World, Vancouver. Coaching the captain: the mentoring process.

62 October 1996 - Signal Transduction Conference, Lake Tahoe, Nevada, USA. Insulin signaling through protein kinase cascades.

63 October 1996 - Insulin Signaling & Diabetes, Washington, D.C. , USA Vanadium compounds for treatment of diabetes in rats.

64 November 1996 - Biochem. Pharma, Laval, QC. Insulin signal transduction through protein kinases.

65 November 1996 - Life Sciences Venture Forum, Toronto, ON. Kinetek Pharmaceuticals Inc.

66 20 December 1996 - Biochemistry, Pharmacology & Physiol. Club of U.B.C.- Vancouver Keynote Speaker - Careers in Biotechnology.

67 7 November 1997 - Dept. of Medicine, Univ. of B.C., St. Paul’s Diabetes Centre. Insulin signalling and organovanandium compounds.

68 23 July 1997 -1997 International Society for Heart Research International Conference, Vancouver. Protein kinase workshop.

69 22 September 1997 - IBC Signal Transduction Therapy, San Diego, CA, USA. Insulin signalling and vanadium compounds for treatment of diabetes in rats.

70 23 June 1997 - University of Calgary, Dept. of Pharmacology, Calgary, AB. Insulin signalling through kinase cascades.

71 18 December 1997 - Dept. of Medicine, University of B.C., St. Paul's Diabetes Centre. Insulin signalling and organovandandium compounds.

72 29 November 1997 - Brain and Spinal Cord Research Centre Symposium. UBC, Vancouver. Signal transduction research.

73 6 June 1998 - Bridging the Straight of Georgia Cancer Conference, Cowichan Bay, BC. Protein kinases for cancer diagnosis and therapeutic targets for chemotherapy.

74 11 June 1998 - Dept. of Pharmacology, University of Virginia, Charlottesville, Virginia, USA. MAP kinases in sea star oocyte cell cycle control.

75 5 March 1998 - Biochemistry, Pharmacology & Physiol. Club of University of BC, Vancouver. Keynote speaker - Career opportunities in the biotechnology industry.

76 7 May 1998 - Association of University Anaethesists Annual General Meeting, San Francisco, CA, USA. Pursuit of scientific excellence in industry.

77 11 March 1999 - Dept. of Physiology, Univ. of B.C. Introduction to protein kinases.

78 8 April 1999 - Dept. of Pharmacology, Univ. of B.C. Introduction to protein kinases.

79 25 June 1999 - American Society for Microbiology Conference, Vancouver. Analysis of protein

kinase networks.

80 24 August 1999 - Pacific Institute for the Mathematical Sciences Symposium, Univ. of B.C. Mathematical analysis of prtoein kinase networks.

81 14 October 1999 - Simon Fraser University - Harbour Centre, Vancouver. Canadian Brain drain to United States.

82 3 February 2000 - Dept. of Pharmacology, University of South Alabama, Mobile, Alabama, USA. MAP kinases in cardiovascular disease.

83 21 February 2000 - UBC Signal Transduction Network, Univ. of B.C. Mapping kineomes - protein kinase network analysis.

84 28 April 2000 - Dept. of Biochemistry, University of Alberta, Edmonton, AB. p38 MAP kinase pathways.

85 6 October 2000 - Montreal Heart Institute, Montreal, QC. Analysis of protein kinase networks in muscle models.

86 14 March 2000 - BC Biotechnology Alliance, Hyatt Regency, Vancouver. Genomics, proteomics and bioinformatics.

87 8 June 2000 - Canadian Society Pharmaceutical Sciences, Crowne Plaza Hotel, Vancouver. Spinning out companies from university research.

88 21 August 2000 - Univ. of B.C. Dept. of Medicine Jubilee CME, Galaxy Cruise, Alaska. What you need to know about molecular biology.

89 30 September 2000 - Foresight Capital Corporation, Delta Resort, Whistler, BC. Human genome project benefits for disease diagnosis and treatment.

90 13 November 2000 - Pacific Rim biotechnology Conference, Hotel Vancouver, Vancouver. The Midas Touch.

91 30 November 2000 - Eldercollege/Capilano College, North Vancouver. How to invest in biotechnology with dollars and sense.

92 30 November 2000 - Biofuture Fund conference, Vancouver. Human genome and personalized medicine.

93 25 January 2001 - PENCE Group, University of Toronto, Toronto, ON. Proteomic analysis of signal transduction pathways.

94 24 April 2001 - Vancouver Enterprise Forum - Proteomics, bioinformatics and personalized medicine.

95 26 April 2001 - Aventis Biotechnology Fair - BCIT, Burnaby - Genomics, proteomics and bioinformatics.

96 27 April 2001 - UBC Department of Pharmacology and Therapeutics - Proteomics analyses of protein kinase networks.

97 28 May 2001 - UBC Department of Biochemistry and Molecular Biology. MAP kinase networks in cell signaling.

98 11 June 2001 - University of Calgary, Calgary, AB. Kinetworks mapping of cell signaling pathways.

99 28 June 2001 - BC Canacer Agency - Advanced Therapeutics Group. Analysis of protein kinase networks.

100 4 October 2001 - UBC Faulty of Medicine Distinguished Lecture. MAP kinase signalling pathways in human cancer.

101 3 July 2001 Institute of Molecular and Cell Biology, National University of Singapore - Proteomic analyses of cell signalling networks: Mapping protein kinase networks.

102 27 February 2002 - Children's Hospital Eastern Ontario, Univ. of Ottawa, Ottawa, ON. Kinetworks proteomics analyses: Mapping protein kinase networks in neural disorders.

103 5 March 2002 - Scripps Institute, San Diego, CA, USA. Kineome analysis: Mapping cell signalling networks.

104 6 March 2002 - International Business Communications - Protein Kinase Drug Discovery Conference, San Diego, CA, USA. Kineome analysis: Mapping protein kinase networks.

105 21 March 2002 - Cambridge Health Institute- Protein to Profits Conference, Munich, Germany. Kinetworks analysis: Mapping cell signalling networks.

106 4 April 2002 - First Forward Network/BC Biotech, Vancouver Terminal City Club. Bioinformatics for Biotech Executives - Keynote talk - A history of Bioinformatics: The past and beyond.

107 12 April 2002 - The Prostate Centre at Vancouver General Hospital Seminar. Mapping cell signalling systems by Kinetworks analysis.

108 26 April 2002 -BC Institute of Technology, Aventis Student Biotech Challenge Talk. Biotechnology in your future.

109 3 June 2002 - 85th Meeting of the Canadian Chemical Society, Vancouver. Drug profiling by Kinetworks analysis.

110 9 September 2002 - IBC 2nd Annual Protein Kinase Conference, Boston, MA, USA Mapping protein kinase pathways by Kinetworks.

111 19 September 2002 - The First Pacific North-West Cell Signalling Conference, Vancouver. Charting protein kinase pathways involved in mitotic checkpoint control.

112 20 September 2002 - The 4th Annual Pacific Northwest Venture Forum- Monte Jade, Vancouver. Kinexus Bioinformatics.

113 9 October 2002 - Laval University, Quebec City, QC. Mapping protein kinase networks.

114 21 November 2002 - BioFuture 2002 Conference and Exhibition, Vancouver. Stress Molecules - Listening to cells to silence disease.

115 29 November 2002 - University of Calgary, Calgary, AB. Promise of proteomics in the post-genomic era.

116 29 November 2002 - University of Calgary, Calgary, AB. Challenge to the entrepreneur scientist in the pursuit of academic excellence and success in the biotechnology industry.

117 3 March 2003 - Strategic Health Institute's Protein Kinase Meeting, San Diego, CA, USA. Kinetworks analysis: Elucidating the cell specific architecture of protein kinase networks.

118 6 March 2003 - Bioinformatics Training Initiative - BC Institute of Technology. Drug discovery in the post-genomics era: The Bioinformatics challenge and opportunity.

119 10 March 2003 - Invest NorthWest Conference, Seattle, WA, USA. Drug target discovery by Kinetworks analysis.

120 19 March 2003 - Cambridge Health Institutes, Molecular Market Place Meeting, Santa Clara, CA, USA. Tracking protein kinase pathways for identification and validation of drug targets.

121 21 March 2003 - Cambridge Health Institute's TriGenome Conference - Santa Clara, CA, USA. Kinetworks analysis: Elucidating the cell-specific architecture of protein kinase networks.

122 29 March 2003 - BC Pharmacy Assoc. Continuing Education Association - Richmond, BC. The

promise of proteomics in the post-genomics era of personalized medicine.

123 4 April 2003 - Eric Hamber Secondary School, Vancouver, BC. Careers in biotechnology.

124 25 April 2003 - British Columbia Institute of Technology - Burnaby, BC. Genomics and proteomics and the future of medicine.

125 29 April 2003 - Pt. Grey Secondary School, Vancouver BC. Careers in biotechnology.

126 29 May 2003 - International Council of Electrophoresis Society on Proteomics: Present perspectives and future challenges. Glasgow, Scotland. Mapping protein kinase pathways in mitotic checkpoint control by Kinetworks.

127 16 June 2003 - University of California San Francisco Cancer Centre, San Francisco, CA, USA. Proteomics analysis of cancer.

128 15 September 2003 - Parkinson's Disease Conference. Painter's Lodge, BC. Proteomics analysis of neurodegenerstive diseases.

129 8 October 2003 - Human Proteome Organization Meeting. Montreal, QC. Tracking protein kinase signalling on macroarrays with antibodies and pepetide antibody mimetics (PAM's).

130 20 October 2003 - Strategic Health Institute - Protein Kinase Meeting – Philadelphia, PA, USA. Mapping protein kinase signalling oathways by Kinetworks analysis.

131 23 October 2003 - IIR Life Science Conference - 2nd Annual Protein Kinase Meeting - Amsterdam, Holland. Monitoring protein kinase networks with arrays of antibodies and peptide antibody mimetics (PAM's).

132 10-17 Jan 2004 - Cambridge Health Institute - PEPTalk Meetin, San Diego, CA, USA. Tracking protein kinases and protein phosphorylation on macroarrays with antibodies and paptide antibody mimetics (PAM's).

133 2+3 March 2004 - GenomeCanada presentation in Toronto, ON.

134 8 March 2004 - Univ. of British Columbia, Robson Square, Public Address for Research Awareness Week. Dr. Professor/Mr. President - The curse of the entrepreneur scientist.

135 9 June 2004 - Cmabridge Health Institute - Protein Kinase targets - Strategies for Drug Development. Boston, MA, USA. Tracking the kinome by multiblotting with antibodies and peptide antibody mimetics (PAM's).

136 19-23 September 2004 - International Business Communications - CHIPS to Hits, Boston MA, USA. Kineome analysis: Mapping protein kinase networks.

137 22-23 Jan. 2005 - Ramandhai Foundation 2nd International Symposium “Current Trends in Pharmaceutical Sciences: Role of Genomics and Proteomics. Ahmedabad, India. (Had to cancel 2 days before departure due to illness)

138 28 Feb. 2005 - Strategic Research Institute – 3rd Annual Protein Phosphorylation Drug Discovery World Summit, San Diego, CA, USA. Tracking the kineome and phosphoproteome in arrays with antibodies and peptide antibody mimetics (PAM’s).

139 14 May 2005 - B.C. Pharmacy Association Annual Meeting, Vancouver. The promise of pharmacoproteomics for disease diagnosis and drug discovery.

140 20 March 2005 - World Congress on Microarray Technology, Vancouver. Tracking the kineome and phosphoproteome in arrays with antibodies and peptide antibody mimetics (PAM’s).

141 13 September 2005 - International Consortium on Anti-Virals Symposium and Workshop, Trent University, Peterborough, ON. Mapping cell signaling pathways.

142 28 September 2005 - National Research Council of Canada Genomics and Health Initiative Annual General Meeting. Ottawa, ON. Commercialization of technology.

143 9 January 2006 - Cambridge Healthtech Institute PepTalk Conference. Coronado, CA. Mapping the phosphoproteome by Kinex™ antibody arrays.

144 24 March 2006 - World Congress on Microarray Technology, Vancouver. Tracking cell signalling protein expression and phosphorylation by antibody microarrays.

145 8 May 2006 - GTCbio Protein Kinases in Drug Discovery Conference. Boston, MA, USA. Tracking the regulation of protein kinases and phosphorylation by quantitative antibody microarrays and multi-immunoblotting.

146 3 July 2006 - IIR's 5th Annual Protein Kinases Congress. Zurich, Switzerland. Kinase pathway analysis for target identification. Chair.

147 26 September 2006 - NRC-Biotechnology Research Institute, Montreal, QC. Meta-analyses of the human kineome and phosphoproteome.

148 2 December 2006 - GTCBio Drug Discovery Meeting. Philadelphia, PA. Antibody multi-immunoblotting and microarray analysis for CNS biomarker discovery in Alzheimer, Parkinson and ALS disease.

149 22 February 2007 - UBC Department of Medicine, Division of Neurology Grand Rounds. Vancouver. Phosphoproteomics and neurodegenerative diseases of the CNS.

150 8 March 2007 - SSP,.PSC.CSCO.WPS Joint meeting. Banff, AB. Mapping cell signalling networks with multi-immunoblotting and antibody microarrays.

151 22+24 May 2007 - Workshop Course - Informa 6th Annual Protein Kinases Congress – Biomarker profiling for kinase target evaluation– Principal Instructor and Coordinator. Lisbon, Portugal

152 18 June 2007 – Frontiers in Bioinformatics Workshop – University of British Columbia, Vancouver. Mapping the human phosphoproteome.

153 30 June 2007 - Workshop Course - World Congress on Microarray Technology, Vancouver. Tracking cell signalling protein expression and phosphorylation by antibody microarrays.

154 29 August 2007 – Seminar Presentation - University of Bath, Bath, UK. Tracking the human phosphoproteome.

155 30 August 2007 – Seminar Presentation - University of Liverpoole, Liverpoole, UK. Tracking the human phosphoproteome.

156 3 September 2007 - Workshop Course - Discovery – Select European Biomarkers Summit and Proteomics Europe Conference. Principal Instructor and Coordinator. Amsterdam, Holland. Mining the kineome and phosphoproteome with protein microarrays for biomarker and drug target.

157 28 October 2007 - Seminar Presentation - Joint meeting of 3rd Czech Proteomic conference and 1st Central and Eastern European Proteomic Conference. Olomouc, Czech Republic. Protein microarrays and phosphoproteomics.

158 6 December 2007 – Seminar Presentation – Lousiana State University Health Sciences Center – Shreveport, LO, USA – Proteomics methodologies.

159 6 December 2007 – Seminar Presentation – Lousiana State University Health Sciences Center – Shreveport, LO, USA – The human kineome and phosphoproteome.

160 9 February 2008 – Visiongain Protein Kinase Conference – London, UK (This meeting was cancelled 4 weeks before, but I was invited as a speaker and chairperson)

161 March 11, 2008 – Max Planck Institute– Berlin, Germany. The human kineome and

phosphoproteome.

162 March 12, 2008 - Informa 7th Protein Kinase Congress – Berlin, Germany. Antibody-based phosphoproteomics for biomarker and drug target identification. (Speaker and panelist)

163 March 27, 2008 - Canadian-Dutch Dementia Colloquium, University of British Columbia, Vancouver. Proteomic approaches for the diagnosis of Alzheimer's disease: What is the rationale and what are the prospects?

164 April 17, 2008 – Department of Biochemistry, Vanderbilt University, Nashville, TN, USA. The human kineome and phosphoproteome.

165 July 4-17, 2008 – In collaboration with the Japanese company Cosmo-Bio, I gave 90 to 120 minute scientific presentations to the following 13 companies. The number of scientists at these presentations ranged from about 6 to 40. The talk was entitled: Tracking the human kineome and phosphoproteome.

Daiichi-Sankyo Pharma (Tokyo)

Ono Pharma (Tsukuba)

Ono Pharma (Osaka)

Astella Pharma (Tsukuba)

Banyu Pharma (Merck) (Tsukuba)

Takeda Pharma (Tsukuba)

Takeda Pharma (Osaka)

Tanabe-Mitsubishi (Saitama)

Japan Tobacco (Osaka)

Dainippon-Sumitomo Pharma (Osaka)

Santen Pharma (Nara)

Shionogi Pharma (Osaka)

Nippon Shinyaku (Kyoto)

167 September 8-10 - Informa Drug Discovery Summer School in Cambridge, UK with Dr. Pelech as an invited speaker and chairperson. (This workshop was cancelled 6 weeks before it was to have transpired).

168 September 24, 2008 - IBC ACT 2008: Protein Kinase Target Conference, San Diego, CA. Mapping the human phosphoproteome. (Speaker, panelist and chair)

169 October 23, 2008 – Omeros Pharmaceuticals, Inc., Seattle, WA, USA. Kinase Inhibitors in the Clinic. Tracking the human kinome and phosphoproteome.

170 February 3, 2009 – University of Washington, Seattle, WA, USA. Breakfast Club Seminar. Tracking the kineome and phosphoproteome.

171 March 3, 2009 – Informa 8th Annual Protein Kinase Congress. Barcelona, Spain. Validation of protein kinase drug targets and drug leads with microarray approaches. (Speaker, panelist and chair)

172 May 8, 2009 – Prostate Centre Grand Round at VGH. Vancouver, BC. Mapping the human kineome and phosphoproteome by protein microarray and bioinformatics analyses.

173 August 6, 2009 – Select Biosciences Microarray World Congress. South San Francisco, CA, USA. Antibody microarrays for biomarker discovery and kinase microarrays for drug screening.

174 December 10, 2009 – Bristol Meyer Squibb. Princeton, NJ, USA. Kinase Inhibitors in the Clinic. Phosphoprotein biomarker and kinase drug target discovery with protein microarrays.

175 February 1, 2010 – University of British Columbia, Coop Program Networking Workshop. Vancouver, B.C.

176 June 21-23, 2010 - Cambridge Healthtech "Next–gen kinase inhibitors: Oncology and Beyond" Meeting. Cambridge, MA, USA. Mapping protein kinase networks and drug interactions with protein microarrays and predictive bioinformatics. (Speaker, panelist and chair)

177 March 24, 2010 – University of British Columbia, Department of Biochemistry Career Workshop. Vancouver, B.C.

178 September 10, 2010 – Global Biomarker Conference & Workshop. Vancouver, B.C. Mapping the human kineome and phosphoproteome with predictive bioinformatics and protein microarrays.

179 September 26 to 30, 2010 - International Society of Hypertension 23rd Scientific Meeting (ISH 2010). Vancouver, B.C. Mapping protein kinase networks for diagnostics and therapeutics development.

180 October 29, 2010 – Select Biosciences – Microarray World Congress, La Jolla, CA, USA. Protein and peptide microarrays for tracking human protein kineome regulation.

181 February 27, 2011 – Student Biotechnology Network. University of Victoria, Victoria, BC. Mapping and tracking the human kineome and proteome.

182 June 9, 2011 – Experimental Medicine Research Day Keynote Talk. University of British Columbia. Vancouver, BC. Confronting the uncertain future of biomedical research and the biotechnology industry in this decade.

183 September 30, 2011 – Select Biosciences – Microarray World Congress. South San Francisco, CA, USA. Protein kinase and phosphosite biomarker discovery and validation with protein microarrays with antibodies, lysates, protein kinases and substrate peptides.

184 February 10, 2012 – Bristol-Meyer-Squibb, Wallingford, CT, USA. Signalling network analyses and biomarker discovery and validation with protein and peptide microarrays.

185 March 7, 2012 – Department of Biochemistry Career Workshop. University of British Columbia. Vancouver, B.C.

186 July 10, 2012 - Merck Molecular Biomarkers: Translational Research Deep Dive Conference. Long Branch, NJ, USA. Tracking the human Kineome, Phosphatome and Phosphoproteome for biomarkers with antibody-based array technologies.

187 July 11, 2012 – Johnson & Johnson Pharmaceuticals. Springfield, PA, USA. Tracking the human Kineome, Phosphatome and Phosphoproteome for biomarkers with antibody-based array technologies.

188 July 12, 2012 - Bristol Myer-Squibb. Princeton, NJ, USA. Tracking the human Kineome, Phosphatome and Phosphoproteome for biomarkers with antibody-based array technologies.

189 July 13, 2012 – Novartis Institute for Biomedical Research Inc., Cambridge, MA, USA. Tracking the human Kineome, Phosphatome and Phosphoproteome for biomarkers with antibody-based array technologies.

190 October 2, 2012 – Purdue University, Department of Biochemistry. West Lafayette, IN, USA. Mapping the human Kineome, Phosphatome and Proteome with cell lysate, antibody and peptide microarrays.

191 March 8, 2013 – University of Missouri, Biochemistry Department. Columbia, MO, USA. Hierarchical molecular, cellular and social intelligence systems in the evolution of life.

192 July 17, 2013 – OMICS Group 3rd International Conference on Proteomics and Bioinformatics. Philadelphia, PA, USA. SigNET KnowledgeBank Workshop.

193 May 29, 2014 – BioConference Live Clinical Diagnostics & Research. On-line, CA, USA. Navigating the complexities of the human oncoproteome with the SigNET KnowledgeBank.

194 August 5, 2014 – OMICS Group 4th International Conference on Proteomics and Bioinformatics. Northbrook (Chicago), IL, USA. Phosphoproteomics and the origin and operations of the kineome. (also session chair)

195 August 6, 2014 – OMICS Group 4th International Conference on Proteomics and Bioinformatics. Northbrook (Chicago), IL, USA. Oncoproteomics for uncovering cancer biomarkers and therapeutics targets. (1 hour workshop)

196 September 10, 2014 – Biochemistry, Biology and Pathology of MAP Kinase II Conference. Vilnius, Lithuania. Navigating human phosphorylation networks with SigNET suite of on-line knowledge bases.

197 September 11, 2014 – Biochemistry, Biology and Pathology of MAP Kinase II Conference. Vilnius, Lithuania. Regulatory roles of conserved phosphorylation sites in the activation T-loop of the MAP kinase ERK1.

198 May 6, 2015 – Division of Neurology, University of British Columbia. Vancouver, BC. The protein kineome: Tracking and manipulating the predominant molecular intelligence system of cells with proteomics and bioinformatics.

199 September 29, 2015 – Human Proteome Organization (HUPO) Conference. Vancouver, BC. Profiling protein expression, modifications and interactions with antibody microarrays.

200 March 14, 2016 – Cure Huntington's Disease Initiative (CHDI) Foundation. Los Angeles, CA, USA. Overview of the Kinexus integrated proteomics and bioinformatics services platform.

201 March 29, 2016 – OMICS Group World Proteomics 6th Meeting. Atlanta, GE, USA. Two oral presentations: The SigNET KnowledgeBank - A series of on-line, open-access proteomics websites for biomarker identification and drug development; Tracking protein expression, modifications and interactions with antibody microarrays. (I also chaired two oral sessions)

202 July 18, 2016 – International Union of Molecular Biology and Biochemistry Meeting. Vancouver, BC. Positive and negative control of protein-serine/threonine kinases by phosphorylation in the catalytic domain T-loop. (I also chaired two oral sessions)

203 February 6, 2017 – Samsung Medical Center. Seoul, Korea. Tracking protein biomarkers in human lung tumour biopsies.

204 February 9, 2017 – 13th Korea Genome Organization (KOGO) Winter Symposium. Vivaldi Park, Korea. Tracking protein expression, modifications and interactions with antibody microarrays.

205 July 24th, 2017 – COSMO Bio. Toyko, Japan. Tracking protein expression, post-translational modifications and interactions with antibody microarrays.

206 July 26th, 2017 – Ono Pharmaceutical. Kyoto, Japan. Tracking protein expression, post-translationa modifications and interactions with antibody microarrays.

207 July 27th and 28th, 2017 – JPrOS 15th JHUPO Conference. Osaka, Japan. Two oral presentations: Tracking protein expression, post-translational modifications and interactions with antibody microarrays; Structure-function analyses of the catalytic domains of eukaryotic protein kinases.

208 August 30, 2017 – Bridging Discovery Research with Therapeutics Conference. Banff, Alberta. Investigations of the multi-site phosphorylation of CTP:phosphocholine cytidylyltransferase in huma

cancer cell lines.

May 1, 2018 – Vancouver, BC. Tracking cell signalling protein expression, post-translation modifications, interactions and activation with antibody microarrays.

July, 2018 – EuroScicon Proteomics Meeting. London, England. Monitoring protein expression, phosphorylation and interactions with high content antibody microarrays. Structure-function studies of the catalytic domains of eukaryotic protein kinases. Meta-analyses of small molecule inhibitors of protein kinases. (Invited chair) (Meeting was cancelled by conference organizers 6 weeks in advance of the meeting)

November 19th and 20th, 2018 – 2nd Global Summit & Expo on Proteomics – 2018. Dallas, Texas. Structure-function studies of the catalytic domains of eukaryotic protein kinases. Monitoring protein expression, post-translational modifications and interactions with high content antibody microarrays Workshop – The open-access suite of bioinformatics websites in the SigNET KnowledgeBank. (Invited chair).

February 12, 2019 - 15th Korea Genome Organization (KOGO) Winter Symposium. Vivaldi Park, Korea. Tracking protein expression, post-translational modifications and interactions with high content antibody microarrays.

February 13, 2019 - Daegu Gyeongbuk Institute of Science and Technology. Daegu, Korea. Trackir protein expression, post-translational modifications and interactions with high content antibody microarrays.

January 15, 2021 – Overview of Kinexus Bioinformatics Corporation and the NDR ALS Biomarker Project. Neurodegenerative Disease Research (NDR), Inc. Group via ZOOM in USA

October 28, 2021 - Dr Steven Pelech - Science or fear vaccine mandates UBC. UBC Students for Freedom of Expression. Vancouver, B.C.

February 2, 2022 – Pandemic of the unvaccinated. Canadian Covid Care Alliance. Live Zoom presentation.

April 9, 2022 – Third Annual Med Ed Conference. Lions Gate Hospital Foundation Youth Advisory Committee. My past and your future in medical research and practice. Vancouver, B.C.

May 7, 2022 – Unity Conference. COVID-19, natural immunity and vaccines. Kelowna, B.C.

May 28 and 29, 2022 - Restore Canada Conference. We Unify Canada. Victoria, B.C.

June 23, 2022 – COVID-19 and natural immunity: Do I need to get vaccinated. Langley, B.C.

June 30, 2022 – Progress report for the Kinexus Bioinformatics Corporation and the NDR ALS Biomarker Project. Neurodegenerative Disease Research (NDR), Inc. Group via ZOOM in USA

September 10, 2022 – Natural versus COVID-19 vaccine-induced immunity. Victory Canada Candlelight Vigil. Vancouver Art Gallery Plaza. Vancouver, B.C.

September 26, 2022 – Conference on Idaho Victims of Pandemic Policy and Law. Prevalence of natural and COVID-19 vaccine induced immunity: What does SARS-CoV-2 antibody testing show Via Zoom in USA.

224 October 1, 2022 – White Rock SDA Church. Natural immunity … Science or science fiction? Part 1 and Part 2. White Rock, B.C.

225 December 10, 2022 – Vancouver Art Gallery Plaza. Natural Immunity versus COVID-19 vaccine-induced immunity. Vancouver, B.C.

226 January 18, 2023 – David Eby Constituent Office. Why Bill 36 is dangerous to our healthcare system. Vancouver, B.C.

227 January 21, 2023 – UBC Cancer Association. The discovery of the molecular basis of cancer. UBC SUB Nest, Vancouver, B.C.

228 January 23, 2023 – Fraserview Community Hall. Natural versus COVID-19 vaccine-induced immunity … The Dwindling case for vaccination. Maple Ridge, B.C.

229 January 29, 2023 – Heritage Hall. Natural versus COVID-19 vaccine-induced immunity … The Dwindling case for vaccination. Canadian Film Workers for Human Rights & Ethics Association Town Hall. Vancouver, B.C.

230 February 4, 2023 - White Rock SDA Church. The crumbling case for COVID-19 vaccination. White Rock, B.C.

231 February 18, 2023 - World Wide Rally for Freedom at 999 Robson Street. Vancouver, B.C.

232 May 3, 2023 – The COVID-19 Pandemic…What Really Happened. Testimony at the National Citizen's Inquiry in Canada's COVID-19 Response. Langley, B.C.

(e) Other Presentations

(f) Other - Poster (only Poster Presentations from 2016 are listed)

1 April 16, 2016 – American Association for Cancer Research Annual Meeting. New Orleans, LA, USA. Steven Pelech, Lambert Yue, Jeff White, Ryan Hounjet, and Dirk Winkler. Profiling signalling protein expression,
modifications and interactions with multi-dimensional antibody microarrays.

2 April, 2016 – Federation of American Societies for Experimental Biology Annual Meeting. San Diego, CA, USA. Two posters: Steven Pelech, Lambert Yue, Jeff White, and Dirk Winkler. Modifications and interactions with multi-dimensional antibody microarrays; Steven Pelech, Lambert Yue, Shenshen Lai, Dirk Winkler, Jane Shi and Hong Zhang. Production and Characterization of polyclonal generic phosphotyrosine-specific antibodies.

3 July 18, 2016 – International Union of Molecular Biology and Biochemistry Meeting. Vancouver, BC. Two posters: Lambert Yue and Steven Pelech - Multi-dimensional analyses of protein expression, modifications and interactions with high content antibody microarrays (PP01.108); Steven Pelech, Shenshen Lai, Javad Safaei and Lambert Yue - Positive and negative regulation of protein-

serine/threonine kinases by their phosphorylation upstream of subdomain VIII in the T-loop (CS02.04).

4

April 2017 – American Association for Cancer Research Annual Meeting. Washington, DC. Poster: Lambert Yue and Steven Pelech - Tracking expression, post-translational modifications and interactions of EGF signalling proteins in A431 cells with antibody microarrays.

5

April 2018 – Canadian National Proteomics Network Annual Meeting. Vancouver, BC. Two posters: Kevin Gonzales, Lambert Yue and Steven Pelech - Phosphorylation of CTP:phosphocholine cytidylyltransferase (PCYT1A); Dirk Winkler, Lambert Yue, Javad Safaei, Zhoung Hua and Steven Pelech - Identification of optimal substrate peptides for protein kinases.

6

October 2019 - Canadian Association of Neuropathologists. Kingston, ON. Poster: Koeppen, A., Travis, A.M., Sutter, C., Pelech, S., and Mazurkiewicz, J.E. - Friedreich cardiomyopathy is a secondary desminopathy.

7

November 13-16, 2019 - International Ataxia Research Conference. Washington, DC. Poster: Koeppen, A.H., Travis, A.M., Qian, J., Mazurkiewicz, J.E., Gelman, B.B., Pelech, S., Sutter, C. The tissue proteome of dorsal root ganglia in Friedreich ataxia.

8.

December 11-14, 2021 - American Society for Hematology. Atlanta, GA. Oral presentation: Yen, R, Yue, L. Pelech, S., Jiang, X. Identification of a highly deregulated eIF4F translation initiation complex in drug-resistant BCR-ABL^{+} cells by a phospho-proteomic antibody microarray.

(g) Conference Participation (Organizer, Keynote Speaker, etc.)

1 1991 - Vancouver organizing committee for 1991 Society for the Study of Reproduction International Conference

2 25 October 1992 - Keystone, Colorado A.S.B.M.B. Symposium, Chairperson

3 1996 - 1997 Vancouver organizing committee for 1997 International Society for Heart Research International Conference

10.1 SERVICE TO THE UNIVERSITY

(a) Memberships on committees, including offices held and dates

Departmental

1 1988 - 2023 - Univ. of B.C. Dept. Medicine - Experimental Medicine Graduate Program Committee

In 2022, I attended two formal meetings of the Committee, reviewed over 80 scholarship applications, as well as faculty and student admissions to the graduate program

2 1993 - 1997 - Univ. of B.C. Department of Medicine Grant Review Committee - Active Member

3 1998 - 2002 - Univ. of B.C. Dept. Medicine - Academic Appointments, Reappointments, Promotions and Tenure Committee, Co-chair

4 July 24, 2000 - VHHSC Grant Panel

5 Brain Research Centre – Space Planning Committee – Meetings: April 8, 2009; May 1, 2009;

Divisional

6 1998 - 2004 - Brain Research Centre - Space Planning Committee - Active Member

7 1987 - 1996 - Univ. of B.C. Biomedical Research Centre - Safety Committee - Active Member

Faculty

8 1998 - 2001 - Faculty of Medicine MD/PhD Graduate Program Committee

9 2000 - 2003 - Faculty of Medicine Research Advisory Committee - Member

10 2003 - 2007 - Faculty of Medicine Senior Academic Appointments, Reappointments, Promotions and Tenure Committee - Member

11 2006-2008 – Faculty of Medicine Internal Reviewer (HeRRO) of grants prior to submission to C.I.H.R. (1 grant per year). In 2008, I reviewed a grant application prepared by Dr. Brian Kwon. He was successful in funding.

12 2004-2008 – TAG Workshop Instructor for Preparation of Teaching Dossiers (2-3 workshops per year). In 2008, one was given on March 5 at VGH and another was given on September 22 at Richmond General Hospital.

13 November, 2014 – Reviewer for VCHRI Top Graduate Doctoral Student Award – Preparation of reports for 7 applicants.

14 April 18, 2017 and May 10, 2017 – Facilitator for UBC Responsible Conduct Course

15 January 23, 2018 and February 6, 2018 – Facilitator for UBC Responsible Conduct Course

University

16 1998 - 2007 - Brain Research Centre - Space Planning Committee - Active Member

17 March 14, 1992 Judge - Second Annual Research Workshop, Reproductive & Developmental Sciences Program, Dept. Obstetrics & Gynaecology, U.B.C.

18 June 22, 2000 - Chairman of the Degree Validation Panel convened to review the Proposal for a joint British Columbia Institute of Technology/University of British Columbia Program for a Bachelor of Science degree in Biotechnology

19 2001 - 2004 - Faculty of Medicine Research Planning Committee - Member

20 2001 - 2003 - University of British Columbia Research Awareness Committee Member

21 May 2, 2001 - Canada Research Chairs Selection Committee Member

22 March 12, 2002 - Vancouver Hospital Health Sciences Centre Salary Awards Panel

23 January 24, 2008 – Judge – UBC Faculty of Dentistry Graduate Research Poster Competition

24 February 27, 2008 – Panelist - UBC Department of Biochemistry and Molecular Biology Careers
25 Evening

March 13, 2014 – Panel member for 2014 Science Career Information Fair (SCIFair) at the Life Sciences Centre, UBC.
26

March 19, 2014 – Panel member for 2014 Biochemistry Careers Night for the Department of Biochemistry and Molecular Biology at the Abdul Ladha Science Student Centre, UBC.

27 January 11, 2017 – Poster judge for the Faculty of Dentistry Graduate Student Program

28 November 7, 2018 – Poster judge for the UBC Faculty of Medicine and VGH Research Expo

29 January 17, 2019 – Panelist – UBC Computer Science/Life Sciences Panel – Careers Evening

30 March 9, 2019 – Panelist and speaker at 2 workshops - Operation Med School Vancouver (OMS) – Career event for high school students at the Robert H. Lee Alumni Centre

31 October 1, 2020 – present – UBC Senate. Faculty of Graduate and Postdoctoral Studies Representation. Also serve on the Senate Admissions Committee, and the Senate Admissions Appeals Committee

(b) Other service, including dates

1 October 25, 1991 Medical Research Council representative for Scholarships Day at UBC

2 September 24, 1992 Medical Research Council Representative for Scholarships Day at UBC

3 October 29, 2008 - Representative for Brain Research Centre for strategic discussion meeting in Waterfront Hotel in downtown Vancouver with Deputy Minister David Molony from Industry Canada to review government support for translational research

4 December 11, 2008 – Representative for UBC for strategic discussion meeting with N.S.E.R.C. at Pinnacle Marriott Hotel in downtown Vancouver to review government support for translational research

5 September 29, 2014 – Panel member for biotechnology curriculum development at the Langara College – Teaching and Curriculum Development Centre

6 October 15, 2020 to December 31, 2022– Panel member for Langara College B.Sc. in Bioinformatics Advisory Committee

Dissertation Committee and Examinations

Ph.D. & M.Sc. Supervisory Committee Membership

1 Dr. Paul Sunga - Dept. of Medicine (1989-1992 until Ph.D.)

2 Dr. Yong Hei - Pharmaceutical Sciences (1990-1993 until Ph.D.)

3 Ms. Elham Ettehadieh - Dept. of Biochemistry (1990-1993)

4 Mr. Brett Gabelman - Dept. of Anatomy (1990-1992 until M.Sc.)

5 Mr. Liren Tang - Dept. of Zoology (1991-1995 until Ph.D. & Ph.D. Examiner)

6 Ms. Rachel Zhande - Dept. of Biochemistry (1991-1998 until Ph.D.)

7 Mr. Aswin Patel - Pharmaceutical Sciences (1992-1996 until Ph.D.)

8 Ms. Patricia Herrera-Velt - Dept. of Microbio. Immunol. (1992-1997 until Ph.D.)

9 Mr. Sep Farahbakhian - Pharmaceutical Sciences (1992-1994 until M.Sc.)

10 Ms. Marie-Terese Little - Dept. Obsteterics & Geynecology (until 1993)

11 Mr. Patrick Tang - Dept. Microbio. Immunol. (1993-1997 until Ph.D.)

12 Mr. Mohammed Hasham - Dept. of Medicine (1994-1995 until M.S.)

13 Ms. Krista McCutcheon - Dept. of Anatomy (1994-1996 until M.Sc.)

14 Mr. Allen Young - Dept. of Oral Biology (1995-1997)

15 Mr. Brent Hehn - Dept. of Oral Biology (1995-1997 until Ph.D.)

Mr. Steven Drew - Dept. of Medicine (1995-1998 until M.Sc.)
Mr. Alaa El-Husseini - Dept. of Psychiatry (1995-1997 until Ph.D.)
Ms. Julia Mills - Dept. of Psychiatry (1995-1998 until Ph.D.)
Ms. Claire Sutherland - Dept. Microbiology Immunology (1995-1999 until Ph.D.)
Ms. Rochelle Starhe - Dept. of Medicine (1996-2001 until Ph.D.)
Mr. Mark Ware - Dept. of Medicine (1996-2000)
Mr. Vijay Viswanathan - Dept. Psychiatry (1998-2004 until Ph.D.)
Mr. Olaf Heisel - Dept. of Medicine (1999-2001 until Ph.D.)
Mr. Godfrey Miles - Dept. of Plant Sciences (1999-present)
Mr. Jan Ehses - Dept. of Physiology (1999-2003 Ph.D.)
Ms. Shu Hong Li - Pharmaceutical Sciences (2000 until 2001 Ph.D.)
Ms. Doris Chiu - Dept. of Medicine (2000-until 2001 M.Sc.)
Ms. Lucy Marzban - Pharmaceutical Sciences (2000 until 2001 Ph.D.)
Ms. Somrudee Sritubtim - Dept. Plant Sciences (2000 until 2005 Ph.D.)
Mr. Steven Drews - Dept. of Medicine (2000-2003 until Ph.D.)
Mr. Farrell MacKenzie - Dept. of Pathology (2001-2003 until M.Sc)
Ms. Jiehong Ju - Dept. of Kinesiology, Simon Fraser University (2001-2004 until Ph.D.)
Ms. Mannie Fan - Neuroscience Program (2002-2008 until Ph.D.)
Ms. Gina Rossi - Dept of Medicine (2002-2010)
Ms. Michelle Woo - Dept. Medicine (2003-2007 until Ph.D.)
Ms. Catherine Tucker - Dept. Medicine (2004-2007 until Ph.D.)
Mr. Tyson Brust – Neuroscience Program (2005-2008 until Ph.D.)
Mr. Philip Ly – Dept. Medicine (2005-2007 until M.Sc.)
Mr. Ebrima Gibbs – Dept. Medicine (2005-2008 until Ph.D.)
Ms. Shirley Chen – Dept. Medicine (2005-2009)
Mr. Scott Widenmaier – Dept. Cellular Physiological Sciences (2006-2010 until PhD)
Mr. Gobind Sun – Dept. Medicine (2006-2007 until transfer to new supervisor)
Ms. Amy Lai - Dept. Medicine (2007-2008 until transfer to new supervisor)
Ms. Arezoo Ostenehe – Dept. Medicine (2009-2013)
Ms. Shenshen Lai - Dept. Medicine (2009-2015 until Ph.D.)
Mr. Dominik Sommerfeld - Dept. Medicine (2010-2012 until transfer to new supervisor)
Mr. Javad Safaei – Dept. Mathematics & Computer Science (2008-2015 until Ph.D.)
Ms. Trisha Kostesky – Dept. Medicine (2010-2011 until M.Sc.)
Mr. Mazyar Ghaffari – Dept. Medicine (2011-2015)
Ms. Valerie Poirier - Dept. Medicine (2011-2015 until Ph.D.)
Mr. Dennis Wong - Dept. Medicine (2011-2013)
Ms. Melissa Richard-Greenblat - Dept. Medicine (2012-2016 until Ph.D.)

53 Ms. Anna Cecilia Sjoestroem – Dept. Medicine (2013-2014 until M.Sc.)
54 Mr. Franco Cavaleri - Dept. Medicine (2014-2017)
55 Mr. Bisher Hassan Abuyassin – Dept. Pharmacology (2015-2018)
56 Mr. Lambert Yue - Dept. Medicine (2016-2020)
57 Mr. Ryan Yen – Dept. Medicine (2017-2022)
58 Ms. Anam Nan Nan Liu – Dept. Pathology and Laboratory Medicine (2017-2019)

Directed Research Studies Supervision

1 Mr. Gordon Cheung – 4th year Zoology (2003-2004) 8 months
2 Ms. Nastaran Mohammadi – 5th year unclassified (2006) 7 months
3 Ms. Sharon Zhao – Department of Mathematics & Computer Sciences, Simon Fraser University. Ph.D. graduate student. Joint MITACS project supervision. (2005-2006) 8 months
4 Mr. Mazyar Ghaffari – 1st year graduate student (2008) 6 months starting March 1
5 Mr. Javad Safaei – Department of Mathematics & Computer Sciences, Simon Fraser University. Ph.D. graduate student. Joint MITACS project supervision. (2008-2015)
6 Ms. Parisa Shoosht – Department of Mathematics & Computer Sciences, Simon Fraser University. Ph.D. graduate student. Joint MITACS project supervision. (2008)
7 Mr. M. Shabab Hossain – Department of Computer Science, University of B.C., M.Sc. graduate student. Joint MITACS project supervision. (2011)
8 Mr. Alireza Davoodi - Department of Computer Science, University of B.C., M.Sc. graduate student. Joint MITACS project supervision. (2013-2014)
9 Ms. Nishima Arora – Biotech Biotechnology, Vellore Institute of Technology, India., undergraduate student. Six months full-time directed research studies (January 1 – June 30, 2015).
10 Mr. Lambert Yue – Department of Biology, University of B.C. 5th undergraduate student. Four months full-time directed research studies (January 1 – April 30, 2016).
11 Mr. Kevin Gonzales – Department of Biology, University of B.C. 5th year undergraduate. Eight months, part-time directed research studies (September 1, 2017-April 30, 2018).
12 Mr. Abiel Kwok – Integrated Sciences Program, University of B.C. 4th year undergraduate. Eight months, part-time directed research studies (September 1, 2019-April 30, 2020).
13 Mr. Kevin Wong – Department of Biology, University of B.C. 3th year undergraduate. Eight months, part-time directed research studies (September 1, 2019-April 30, 2020).

B.Sc. Honours Thesis Examiner

1 Ms. Maryam Baghannazary - Dept. of Biology (1992)
2 Mr. Danny Leung - Dept. of Biochemistry, Simon Fraser University (1994)
3 Ms. Monika Aluweilla - Dept. of Biochemistry, Simon Fraser University (1995)

M.Sc. Thesis Examiner

1 Mr. Jonathan Kao - Dept. of Medicine (1990)
2 Ms. Rachel Zhande - Dept. of Biochemistry (1991)
3 Mr. Peter Dreyden - Dept. of Medicine (1992)
4 Mr. John Stingl - Dept. of Anatomy (1992)
5 Mr. Brett Gabelman - Dept. of Anatomy (1992)
6 Mr. Sep Farahbakhian - Pharmaceutical Sciences, U.B.C (1994)
7 Mr. Mohammed Hasham - Dept. of Medicine, UBC (1996)
8 Ms. Krista McCutcheon - Dept. of Anatomy, UBC (1996)
9 Mr. Steven Drew - Dept. of Medicine (May 19, 1998)
10 Ms. Shu Hong Li - Pharmaceutical Sciences, UBC (May 23, 2000)
11 Mr. Tom Yokogawa - Dept. of Medicine (October 10, 2000)
12 Ms. Doris Chiu - Dept. of Medicine (October 4, 2001)
13 Mr. Farrell Mackenzie - Dept. Pathology (April 23, 2003)
14 Mr. Geoff Karjala – Dept. of Biochemistry & Molecular Biology (November 30, 2004)
15 Mr. Philip Ly – Dept. of Medicine (October 9, 2007)
16 Ms. Trisha Kostesky – Dept. Medicine (June 21, 2011)
17 Ms. Anna Cecilia Sjoestroem – Dept. of Medicine (October 7, 2013)
18 Ms. Anam Lui - Dept. of Medicine (September 30, 2019)

Ph.D. Oral Comprehensive Examiner
1 Ms. Marie Terese Little - Dept. Obstetrics & Gynaecology (June 10, 1991)
2 Dr. Amanda Jones - Dept. Medicine (December 11, 1991)
3 Ms. Patricia Herrarez - Dept. Microbiol. Immunol. (December 14, 1992)
4 Ms. Julia Mills - Dept. Psychiatry (June 21, 1995)
5 Mr. Alaa El-Husseini - Dept. Psychiatry (January 24, 1996)
6 Ms. Rochelle Starhe - Dept. of Medicine (May 27, 1997)
7 Mr. Olaf Heisel - Dept. of Medicine (2000)
8 Mr. Vijay Viswanathan - Dept. Psychiatry (June 15, 2000)
9 Mr. Godfrey Miles - Dept. Plant Sciences (September 15, 2000)
10 Mr. Jan Ehses - Dept. of Physiology (November 21, 2000)
11 Mr. Mohamed Sayed - Dept. of Medicine (December 19, 2000)
12 Mr. Steven Drews - Dept. of Medicine (February 7, 2001)
13 Mr. Kelvin Chang - Dept. of Obstetrics and Gynaecology (April 17, 2002)
14 Ms. Gina Rossi - Dept. Medicine (Sept 17 and Nov 10, 2004)
15 Mr. Gobind Sun – Dept. Medicine (May 28, 2007)
16 Mr. Scott Weidermaier – Dept. of Physiology (September 30, 2008)
17 Ms. Arezoo Astenehe – Dept. of Medicine (April 17, 2009)

18 Mr. Dennis Wong – Dept. of Medicine (September 30, 2009)
19 Mr. Darryl Bannon - Dept. of Medicine (November 10, 2011)
20 Ms. Valerie Poirer - Dept. of Medicine (November 25, 2011)
21 Ms. Shenshen Lai - Dept. of Medicine (December 14, 2011)
22 Mr. Darryl Bannon - Dept. of Medicine (May 17, 2012)
23 Ms. Joanna Triscott - Dept. of Medicine (June 4, 2012)
24 Ms. Melissa Richard – Dept. of Medicine (February 7, 2013)
25 Mr. Franco Cavaleri – Dept. of Medicine (April 17, 2015)
26 Mr. Bisher Hassan Abuyassin – Dept. of Medicine (December 12, 2016)
27 Mr. Ryan Yen – Dept. of Medicine (January 17, 2019)

Ph.D. Thesis Examiner

1 Mr. Grant Hatch - Dept. of Biochemistry, University of Manitoba (1989)
2 Dr. Poul Sorenson - Dept. of Pathology, UBC (1990)
3 Ms. Alice Mui - Dept. of Pathology, UBC (1992)
4 Mr. Paul Sunga - Dept. of Medicine, UBC (1992)
5 Dr. Jong Hei - Pharmaceutical Sciences, UBC (1993)
6 Mr. Guy Mordret - Dept. of Biochemistry, University of Brest, France (1993)
7 Ms. Corinne Reimer - Dept. of Anatomy, UBC (1994)
8 Mr. John Hill - Dept. of Pathology, UBC (1994)
9 Ms. Ruth Lanius - Dept. of Opthomology, UBC (1994)
10 Mr. Ashwin Patel - Pharmaceutical Sciences, UBC (1996)
11 Mr. Patrick Rebstein - Dept. of Microbiol. Immunol., UBC (1996)
12 Ms. Patricia Herrera-Velt - Dept. Microbio. Immunol, UBC (1997)
13 Mr. Xi-Long Zheng - Dept. of Medical Biochemistry, University of Calgary (June 23, 1997)
14 Mr. Vuk Stambolic - Dept. of Biochemistry, University of Toronto (August 7, 1997)
15 Mr. Alaa El-Husseini - Dept. of Psychiatry, UBC (October 17, 1997)
16 Ms. Rachel Zhande - Dept. of Biochemistry, UBC (December 1, 1997)
17 Mr. David Ng - Dept. of Microbio. Immunol., UBC (April 24, 1998)
18 Mr. Jeffrey Posaconi - Dept. of Chemistry, UBC (June 19, 1998)
19 Ms. Adrienne Boone - Dept. Biochemistry, UBC (April 5, 2000)
20 Ms. Zahara Jaffer - Dept. Microbiol. & Immunology, UBC (August 14, 2000)
21 Mr. Abdulaziz Al-Fahim - Dept. of Medicine, UBC (August 11, 2000)
22 Ms. Ravenska Wagey - Dept. of Medicine (December 14, 2000)
23 Ms. Amy Dambrowitz - Dept. of Biochemistry (June 6, 2001)
24 Ms. Rochelle Heisel - Dept. of Medicine (July 30, 2001)

25 Ms. Lucy Marzban - Faculty of Pharmaceutical Sciences (September 6, 2001)
26 Mr. Mohamed Sayed - Dept. of Medicine (October 26, 2001)
27 Ms. Xiaoli Cheng - Dept. of Biochemistry (December 10, 2002)
28 Mr. Steven Drews - Dept. Medicine (June 24, 2003)
29 Mr. Jan Ehsus - Dept. Physiology (July 18, 2003)
30 Mr. Kelvin Cheng - Dept. Gynaecology and Obstretics (Feb 4, 2004)
31 Ms. Sherri Christian - Dept. Microbiology and Immunology (May 5, 2004)
32 Ms. Elizabeth Slow - Dept. Medicine (November 26, 2004)
33 Ms. Rita Maghsoodi – (January 17, 2005) - Chair
34 Ms. Tanya Griffith – Department of Biochemistry and Molecular Biology (January 27, 2006) - Chair
35 Ms. Zhou Hongyan – University of Hong Kong (November 12, 2006) – External Examiner
36 Ms. Justine Karst – Department of Botany (July 9, 2007) - Chair
37 Mr. Robert Ferdman – Department of Astronomy (December 13, 2007) - Chair
38 Ms. Catherine Tucker – Department of Medicine (December 21, 2007)
39 Ms. Jin Suk Lee – Department of Botany (January 18, 2008) – University Examiner
40 Mr. Ebrima Gibbs – Dept. of Medicine (August 22, 2008)
41 Mr. Mark Romanish – Faculty of Science (July 22, 2009) – Chair
42 Mr. Douglas Sweeney – Faculty of Engineering (Nov. 12, 2009) - Chair
43 Mr. Scott Widenmaier – Dept. Cellular Physiological Sciences (June 30, 2010)
44 Mr. David Morin – Dept. of Medicine (December 22, 2011) - Chair
45 Ms. Grace Lee Kam – Dept. of Medicine (December 23, 2011)
46 Ms. Valerie Poirier – Dept. of Medicine (January 23, 2015)
47 Mr. Too Jin Park – Dept. of Medicine (February 10, 2015)
48 Ms. Shenshen Lai – Dept. of Medicine (March 25, 2015)
49 Mr. Javad Safaei – Dept. of Computer Science and Mathematics (April 9, 2015)
50 Ms. Melissa Richard – Dept. of Medicine (June 28, 2016)
51 Ms. Sylvia Cheung – Dept. of Surgery (September 15, 2016)
52 Mr. Saleem Iqbal – Crystallography and Biophysics, University of Madras, Chennai, India (November 9, 2018) – External Examiner
53 Mr. Bisher Hassan Abuyassin – Dept. of Medicine (December 21, 2018)
54 Mr. Ryan Yen – Dept. of Medicine (August 25, 2022)
55 Mr. Andrew Santos – Dept. Microbiology and Immunology (December 15, 2022)

10.2 SERVICE TO THE HOSPITAL

(a) Memberships on committees, including offices held and dates

(b) Other service, including dates

11. SERVICE TO THE COMMUNITY

(a) Memberships on scholarly societies, including offices held and dates

1 1990-present Canadian Society for Biochemistry and Molecular Biology - Active Member

2 1990-1992 Society for the Study of Reproduction (on local organizing committee for 1991 S.S.R. International Conference)

3 1996-1997 International Society for Heart Research (on local organizing committee for 1997 I.S.H.R. Conference)

4 1996-1999 American Society for Microbiology - Active Member

5 2016-2018 American Society for Biochemistry and Molecular Biology – Active Member

(b) Memberships on other societies, including offices held and dates

1 1980-1987, Canadian for Health Research - Active Member

2 1996-2002, 2008 Vancouver Public Aquarium - Active Member

2021-present, Vice-President, Chair of the Scientific and Medical Advisory Panel, Canadian Covid Care Alliance

(c) Memberships on scholarly committees, including offices held and dates

1 1992-present Lunar Society - Active Member

(d) Memberships on other committees, including offices held and dates

1 1980-1983 - Executive Committee of B.C. Chapter of Canadian for Health Research

2 1991-1993 - M.R.C. of Canada Studentship Committee

3 1991-1994 – Canadian Heart & Stroke Foundation Operating Grant Panel

4 1994-1995 - Committee for West Vancouver High Schools Cooperative Education Program

5 1994- M.R.C. of Canada Program Grant Committee

6 1994- American Heart Association Grant Panel

7 1995-1996 -M.R.C. of Canada Operating Grant Committee - Biochem. Mol. Biol. Panel B

8 May 29-31, 2000 - Invited Member Strategic Planning Committee for the National Research Council of Canada Industrial Research Assistance Program

9 November 6-9, 2000 - Canadian Institute for Health Research - Operating Grant Committee - Cardiovascular Panel

10 July 31, 2001 - Michael Smith Foundation for Medical Research Senior Scholars and Scientist Award Committee

11 2001 - 2006 - Member Advisory Committee for the National Research Council of Canada Industrial Research Assistance Program

12 2001-2006 - Genome Prairie Scientific Advisory Board

13 2002 - 2007 - Simon Fraser University Biotechnology Advisory Council - Member

14 2003-2005 - Canadian Bioinformatics Resource Initiative - Chairman

15 2004-2010 - National Research Council of Canada Genome Health Initiative Expert Panel. In 2009, I attended the Annual Meeting of the GHI in Montreal in June 1st and 2nd, and provided mid-term reviews of 5 GHI projects for the NRC at an Expert Panel Meeting in Ottawa on December 6. In 2010, I judged new GHI projects on September 27 & 28 in Ottawa.

16 2005-2007 - Simon Fraser University Master of Technology Advisory Board

17 2005 - U.S. National Institutes of Health Director's Roadmap Initiatives, Technology Centers for Networks and Pathways (TCNP) Grant Panel (I was invited to join this panel again in 2008, but declined due to a timing conflict.)

18 2006 – Alberta Cancer Board Grant Review Panel for Programs of Distinction

19 2009 – Canadian Institutes for Health Research - Catalyst Grant: Invention and High-Risk, High-Benefit Research Panel. June 3-5 in Ottawa.

20 2010 – Canadian Institutes for Health Research - Catalyst Grant: Invention and High-Risk, High-Benefit Research Panel. June 3-5 in Ottawa.

21 2021 – 2022 Langara University Bioinformatics Advisory Committee

(e) Reviewer (journal, agency, etc. including dates) - Peer-reviewer of grant-in-aid applications

(g) External examiner (indicate universities and dates)

1 1989 Ph.D. Defence of Grant Hatch - Dept. of Biochemistry, Univ. of Manitoba
2 1993 Ph.D. Defence of Guy Mordret - Dept. of Biochemistry, Univ. of Brest, France
3 1997 Ph.D. Defence of Xi-Long Zheng - Dept. of Medical Biochemistry, Univ. of Calgary
4 1997 Ph.D. Defence of Vuk Stambolic - Dept. of Biochemistry, Univ. of Toronto
5 2006 Ph.D. Defence of Zhou Hongyan - Department of Biochemistry, Univ. of Hong Kong
6 2018 Ph.D. Defence of Saleem Iqbal – Crystallography and Biophysics, Univ. of Madras, Chennai, India

(h) Consultant (indicate organization and dates)

1 1991-1999 Upstate Biotechnology Inc., Lake Placid, N.Y.

2 1995-present Kinections Consulting Ltd, Richmond, B.C.

3 1995-1999 Biozyme, Vancouver, B.C. (member of scientific advisory board)

4 1996-2000 Viratest, Burnaby, B.C. (member of scientific advisory board)

5 1997-2000 StressGen, Victoria, B.C.

6 1999 - present Kinexus Bioinformatics Corporation, Vancouver, B.C. (member Board of Directors)

7 2001 - 2006 GenomePraire Scientific Advisory Board

8 2001 - ARC Pharmaceuticals, Vancouver BC (member of Scientific Advisory Board)

9 2018 - present – GLG, Austin, Texas and London, UK (member of advisory council for industry)

10 2020 – present – Neurodegenerative Disease Research, Inc. (member of research consortium)

(i) Other service to the community

1 1990-present - Cooperative Education Program - Simon Fraser University

2 1991-2007 - Scientist in The School Program - coordinated by Science World

3 1992 – 2010 - Cooperative Education Program - University of Victoria

4 March 9, 1993 - Volunteer for Careers Presentation - Science World, Vancouver.

5 February 14, 1993 - Scientists and Innovators in the Schools, Kitsilano Secondary School, Vancouver

6 1994-present - Cooperative Education Program - West Vancouver Secondary Schools

7 1994-present - Mentor for B.C. Institute of Technology Biotechnology Program

8 1996-present Cooperative Education Program - University of B.C.

9 March 1, 1996 - Volunteer for Careers Presentation - Science World, Vancouver.

10 January 24, 1997 - Scientists & Innovators in the Schools, Gladstone Secondary School, Vancouver.

11 April 2, 1998 - Judge for 1998 Greater Vancouver Regional Science Fair at the University of BC

12 February 4, 1999 - Judge for 1999 BC Biotechnology Alliance Awards

13 April 8, 1999 - Judge for 1999 Greater Vancouver Regional Science Fair at the University of BC

14 April 19, 1999 - Judge for 1999 Caunaught Biotechnology Science Fair, Vancouver

15 February 8, 2000 - Judge for 2000 BC Biotechnology Alliance Awards

16 April 6, 2000 - Judge for 2000 Greater Vancouver Regional Science Fair at the University of BC

17 2001 - Judge for 2001 Aventis Biotechnology Science Fair

18 February 1, 2001 - Judge for 2001 BC Biotechnology Alliance Awards

19 April 26, 2001 - Judge for 2001 Aventis Biotechnology Science Fair

20 March 2002 - Scientists & Innovators in the Schools, University Hill Secondary School, Vancouver.

21 2002 - Judge for 2002 Aventis Biotechnology Science Fair

22 January 17, 2019 - Invited Panelist – UBC Computer Science/Life Sciences Panel –
23 Careers Evening

March 9, 2019 - Invited Speaker at Operation Med School Vancouver (OMS) Workshop for
24 high school students. Career mentoring workshop (2 x 30 minute sessions) held at the Robert H. Lee Alumni Centre at UBC

September 1, 2020 – present – Langara College Bioinformatics Advisory Board member

12. AWARDS AND DISTINCTIONS

(a) Awards for Teaching (indicate name of award, awarding organizations, date)

1 2001 Faculty of Medicine Distinguished lecturer - Basic Sciences

(b) Awards for Scholarship (indicate name of award, awarding organizations, date)

2 1975 Killarney Secondary School Scholarship, Killarney Sec. School, Vancouver

3 1975 B.C. Government Scholarship, Killarney Sec. School, Vancouver

4 1977 Canadian Found. for Diseases of the Liver Summer Studentship, Univ. of B.C.

5 1978 Natural Sciences and Engineering Research Council of Canada Postgraduate Scholarship, Univ. of B.C.

6 1979-1982 Medical Research Council of Canada Studentship, Univ. of B.C.

7 1982 Univ. of B.C. Graduate Student Speaker Competition (1st Place)

8 1982 Izaak Walton Killam Postdoctoral Fellowship

9 1982-1984 M.R.C. of Canada Postdoctoral Fellowship

10 1985 M.R.C. of Canada 1967 Centennial Fellowship

11 1988-1993 M.R.C. of Canada Scholarship Award

12 1993-1996 M.R.C. of Canada Scientist Award

13 1996-1998 M.R.C. of Canada Industrial Scientist Award

(d) Other Awards

14 1993 Canadian Soc. for Biochem. & Molec. Biol. Merck-Frosst Award - for outstanding research in the area of biochemistry and molecular biology in Canada

15 1993 Martin M. Hoffman Award - Univ. of B.C. Hospital Site for Research in Dept. of Medicine

16 1996 Business in Vancouver Top Forty Under Forty Award for Business Achievement

17 1998 International Who's Who

18 2001 Faculty of Medicine 2001 Distinguished Lecturer, University of BC

Fellowship Awards (won by Post-Doctoral Fellows under supervision)

19 Lefebrve, D. - MRC Fellowship 1995-1996

20 Sahl, B. -MRC Fellowship 1995-1997

21 Bhanot, S. - BC Heart & Stroke Fellowship 1995-1997

22 Bhanot, S. - MRC Fellowship (declined) 1995-1997

23 Koide, B. - MRC Fellowship 1995

24 Xu, Yan-Jun - MRC Fellowship 1998-1999

25 Zhang, Hong - NSERC Industrial Fellowship 2003-2004

Studentship Awards (won by Graduate Students under supervision)

26 Palaty, C. - NSERC Studentship 1991-1994

27 Samiei, M. - MRC Studentship 1992-1994

28 Charest, D. L. - Walter Babicki Studentship 1992

29 Charlton, L. - NSERC Studentship 1992-1995

30 Charest, D. L. - MRC Studentship 1993-1997

31 Morrison, D. L. - MRC Studentship 1993-1997

32 Tudan, C. - MRC Studentship 1993-1996

33 Kim, S. - MRC Studentship 1993-1997

34 Palaty, C. - Walter Babicki Studentship 1995

35 Charlton, L. - Killam Studentship 1996-1997

36 Wagey, V. - University Graduate Fellowship 1997-1998

37 Marotta, A. - Evelyn Martin Fellowship 1998-1999

38 Sayed, M. - MRC Studentship 2000-2002

39 Shenshen Lai – University of B.C. Graduate Fellowship 2010-2014

40 Lambert Yue – UBC Experimental Medicine Graduate Program Entrance Award (2016); NSERC Graduate Fellowship 2017-2018; UBC 4YF Scholarship 2018-2020

41 Hamidreza Galavi - UBC Experimental Medicine Graduate Program Entrance Award (2020); UBC 4YF Scholarship 2020-2023; Vanier Award 2022-2024

13. OTHER RELEVANT INFORMATION (Maximum One Page)

1992-1998 - President, CEO and major stock owner of Kinetek Pharmaceuticals, Inc.

Kinetek was a private, early stage biotechnology company that employed 15 Ph.D./M.D. level scientists and 25 other technical and other supporting personnel at the time that I left the company. It was engaged in the discovery and development of drugs for the treatment of cancer, diabetes and other chronic diseases of aging. The Kinetek activities occupied over 18,000 square feet at two locations in south Vancouver. It was acquired by QLT, Inc. in 2004.

1995 - present - President and major stock owner of Kinections Consulting Ltd.

Kinections is a private company that provides consulting advise related to cellular signal transduction and the biotechnology industry. Its services also include the preparation of scientific reports and illustrations.

1999 - present - Founder, President, Chief Scientific Officer and major stock owner of Kinexus Bioinformatics Corporation

Kinexus Bioinformatics is a private company that provides analytical services related to the tracking of protein kinases and bioinformatics related to protein kinases. It has provided proteomics services to over 2000 laboratories in 40 countries. Over 200 of the company's clients are in companies. Twenty-nine of the top 30 pharmaceutical companies in the world are clients of Kinexus.

2021 – present – Founder, Vice-President, Co-Chair of the Scientific and Medical Advisory Committee (SMAC) of the Canadian Covid Care Alliance (CCCA). The CCCA was founded to provide balanced, evidence-based and scientifically sound analyses of recommendations related to COVID-19 with respect to it diagnosis, prevention and treatment. It has over 1600 members across Canada, which includes over 600 research scientists, professors, medical doctors and other health practitioners, and lawyers amongst other professionals. I participate in weekly meetings throughout the year, Tuesdays 4:00 pm - 5:00 pm – SMAC meetings, Tuesdays 5:00 pm - 8:00 pm – Steering Committee meetings, Wednesdays 5:00 pm - 8:00 pm – General Membership meetings.

v. PATENTS

1. PELECH, S.L. Algorithm for elucidation of structure of protein kinase networks. U.S. Issued 2005. (also issued in United Kingdom 2007). This patent describes an algorithm to map out cell signalling pathways using the data collected from the quantifying protein levels in diverse cell/tissue extracts using the Kinetworks™ methodology that was developed in my UBC lab and licensed to Kinexus.

2. PELECH, S. L., Feldman, H., and Zhang, H. Biomarkers of Alzheimer's Disease. US Provisional Application – Jan. 30, 2008.

3. Shapira, T., Rens, C., Puchler, V., Rees, W., Steiner, T., Jean, F., Winkler, D., Sarai, I., PELECH, S., Av-Gay, Y. Inhibition of glycogen synthase kinase-3-beta (GSK3) blocks nucleocapsid phosphorylation and SARS-CoV-2 replication. Provisional Application to UBC UILO in November 2021.

vi. WEBSITES

In the last few years, I have begun to develop on-line, open-access databases and knowledgebases with comprehensive information on proteins, their mRNA and protein expression as well as their phosphorylation. While many people have been involved in the coding of the interfaces for these websites, I have personally devoted much of my time into their conception, design, data annotation, data inspection and coordinating their production. The following is a listing of these websites.

1. KiNET-IB – Kinetworks™ Immunoblotting DataBase (www.kinet.ca)
   First in 2006, KiNET-IB features over 200,000 measurements of the expression and phosphorylation states of hundreds of signal transduction proteins from over 6000 Kinetworks™ multi-immunoblots performed with control and treated tissue/cell samples. Immunoblotting remains the gold standard for protein quantification and the Kinetworks™ methodology was originally developed in my UBC lab. KiNET-IB is a useful tool for evaluating proteins that may participate in the control of diverse cellular processes and their connection with other proteins in signaling pathways. Over 95% of this data has been previously unpublished.

2. KiNET-AM – Kinex™ Antibody Microarray DataBase (www.kinet-am.ca)
   First launched in 2011, KiNET-AM features the quantitative results from nearly 2000 Kinex™ Antibody Microarray analyses with over 1.5 million measurements of 650 to 800 hundred different signalling proteins and phosphosites tracked per microarray. The data can be queried based on biological samples, treatments, specific proteins and phosphosites. Over 98% of this data has not been previously unpublished and was produced from analyses performed at Kinexus.

3. PhosphoNET – Human Phosphorylation Site KnowledgeBase (www.phosphonet.ca)
   First launched in 2010, PhosphoNET is the world's largest repository of known and predicted information on human phosphorylation sites, their evolutionary conservation and the identities of protein kinases that may target these sites. PhosphoNET presently holds data on over 970,000 known and putative phosphorylation sites (P-sites) in over 20,000 human proteins that have been collected from the scientific literature and other reputable websites. Over 177,000 of these phosphosites have been experimentally validated. The rest have been predicted with a novel Phosphosite Predictor algorithm developed at Kinexus. With the PhosphoNET Evolution module, this website also provides information about cognate proteins in over 20 other species that may share these human phospho-sites. This helps to define the most functionally important phosphosites as these are expected to be highly conserved in nature. With the Kinase Predictor module, listings are provided for the top 50 human protein kinases that are likely to phosphorylate each of these phospho-sites using another proprietary kinase substrate prediction algorithm that I helped to develop at Kinexus. With the Phosphosite Match module added in 2017, it is possible to identify phosphosites that are highly related in amino acid sequence. This helps to identity phosphosites that may be detected in cross-reactive off target proteins with phosphosite-specific antibodies. Over 8 million kinase-substrate phospho-site pairs are quantified in PhosphoNET, and over 200 signalling pathway maps are available.

4. TranscriptoNET – Human mRNA Expression KnowledgeBase (http://207.150.202.175)

First launched in 2011, TranscriptoNET features comprehensive information on the mRNA expression levels of about 21,000 genes in about 600 types of human organs, tissues and cells as measured with gene microarrays. The original data used in TranscriptoNET was retrieved from the National Center for Biotechnology Information Gene Expression Omnibus (NCBI GEO), which serves as a repository of experimental gene microarray results submitted by diverse academic and industrial laboratories around the world. We normalized the data from over 900 different studies with over 6000 biological specimens to permit investigations of gene expression and potential interactions that can only be undertaken with such a large dataset of over 125 million gene expression measurements. This normalization process was based on the identification of 60 genes that were commonly and highly expressed in all of the biological samples. This site was first posted in 2013.

5. DrugKiNET – Human Kinase Drug Interaction KnowledgeBase (www.drugkinet.ca)
First launched in 2013, DrugKiNET is an open-access, online resource to foster the identification and characterization of inhibitors of protein kinases for academic and industrial research. It features comprehensive information on over 850 compounds that have been experimentally determined to inhibit human protein kinases. This includes the retrieval of the lowest reported compound IC50, Ki and Kd values from several sources, including the National Center for Biotechnology Information (NCBI) PubChem Compound database, the Kinase SARfari database from the European Molecular Biology Laboratory (EMBL) European Bioinformatics Institute, The International Centre for Kinase Profiling at the University of Dundee, Ambit Biosciences and hundreds of original research publications. In some cases, estimates for IC50 values were derived from limited measurements of kinase inhibition at only one to three different concentrations of the compounds. Using over 105,000 experimentally tested, non-redundant kinase-compound pairs for training, we have developed two kinase inhibitor prediction algorithms to further predict another 200,000 kinase-compound interactions. In 2017, we added a new module to DrugKiNET that provides information on the bond distances between the atoms of over 1500 drugs and the atoms in protein kinases as determined from their x-ray crystallographic structures.

6. OncoNET – Human Cancer Protein KnowledgeBase (www.onconet.ca)
This website features comprehensive information on the mutations and mRNA expression levels for about 3,000 genes in diverse types of human cancers. The mRNA expression data used in OncoNET was originally retrieved from the National Center for Biotechnology Information Gene Expression Omnibus (NCBI GEO), which serves as a repository of experimental gene microarray results submitted by diverse academic and industrial laboratories around the world. We normalized the data from hundreds of different gene microarray studies using a normalization protocol based on the identification of 60 genes that were commonly and highly expressed in all of the biological samples. To explore the mutation of human cancer-related genes, we relied primarily on the collection of data from the Wellcome Trust Sanger Institute's Catalogue of Somatic Mutations in Cancer (COSMIC) database. Further information on these genes and their encoded proteins was annotated from several other sources, including UniProt and the Atlas of Genetics and Cytogenetics in Oncology and Haematology websites. I have used this database to identify new potential oncogenes, tumour suppressor genes and tumour requiring protein genes. This site was first posted in 2013.

7. KinaseNET – Human Protein Kinase KnowledgeBase (www.kinasenet.ca)
KinaseNET features comprehensive information on 536 human protein kinases, including their primary and tertiary structure, regulation, distribution, evolutionary conservation, protein substrate targets, pathway maps, sensitivities to compounds and linkages to human diseases. Each protein

kinase is represented with a separate webpage. KinaseNET also serves as a portal to many other useful websites with additional data about protein kinases. This site was first posted in 2015 and updated in 2017.

8. Kinetica Online – E-journal for Intelligence Systems Research (www.kinexus.ca/kinetica)
This website has not yet been officially launched, but a beta-version is available for viewing since 2013. This unique resource features commentaries, original research publications, databases and knowledgebases, and it also serve as portal to hundreds of other websites that should be useful to researchers engaged in the investigation of cell signalling. All of the articles in Kinetica Online have been published elsewhere.

9. KinATLAS – Human Protein Interaction Altas
(http://kinatlas.ca:8080/KinAtlas/KinaseDrugQuery.html)
This website is in development and a beta version with the first (Kinase-drug interactions) and second modules (Protein-protein interactions) are available for viewing since 2016. The underlying database is complete, and the web interface is still in the process of being coded for the third module (Kinase-substrate interactions). It will show tissue/cell-specific maps of protein-protein and kinase-drug interactions. The kinase-substrate interactions are prioritized using our updated kinase prediction algorithms, and the viewer will contain filters to permit generation of more customized maps.

10. DrugProNET – Human Protein – Drug Interaction KnowledgeBase (www.drugpronet.ca)
This website provides for the identification of the most critical atomic interactions between drugs and their protein targets based on 3D x-ray crystallographic analyses. Defining the key amino acid residues for drug binding in proteins permits the prediction of specific mutations in human genomes that will affect the sensitivities of individuals to these compounds. The bond distances in Angstroms between the closest protein and drug atoms in each crystal complex are provided in downloadable tables, along with definition of the closest amino acid residue side-chains. The single nucleotide variants (SNV's) that would affect these critical amino acid residues involved in drug interactions are also identified in DrugProNET. This website features comprehensive information on over 2000 compounds that have been co-crystallized with over 480 different human proteins in over 4400 protein-compound structures retrieved from the Research Collaboratory for Structural Bioinformatics (RCSB) Protein Databank (PDB).

11. KiNector – Human Protein Kinase-Protein Substrate+Phosphosite Interaction KnowledgeBase (www.kinector.ca)
Over 21,450 human kinase-substrate relationships (KSRs) were retrieved from several sources, including the PhosphoNET, PhosphoSitePlus and PhosphoNetworks websites and the scientific literature. The data are presented in a graphic format as maps, and full functional information was provided for at least 6000 of these KSRs. KiNector shows both direct and indirect linkages between a starting protein kinase and a phosphoprotein target that acts downstream in signalling pathways. KiNector also serves as a portal to other reputable websites that contain detailed information on these kinases and substrates, and provides direct links to the Kinexus Products website, which features over 3500 images of full Western blots performed with lysates from diverse rodent tissue panels and human cancer cell lines.

vii. ARTISTIC WORKS

1. Smith, J., Xu, Y., and PELECH, S.L. Human protein kineome. (2006) [This is a large wall chart that contains the identification of all of the known domains and phosphorylation sites in 515 human protein kinases. It was printed and distributed by Kinexus Bioinformatics Corporation.]

2. PELECH, S.L. and Bowyer, C. The human operating system. (2008) [This is a large wall chart that features over 180 cell signalling pathways. It was printed and distributed by Kinexus Bioinformatics Corporation.]

4. PELECH, S.L, Smith, J., and Xu, Y. Human protein kineome. (2010) [This is an updated, large wall chart that contains the identification of all of the known domains sites in 515 human protein kinases, along with Uniprot, size and substrate specificity information. It was printed and distributed by Kinexus Bioinformatics Corporation.]

5. PELECH, S. L. Human Cancer Protein Interaction Network. (2017). This is a wall chart that shows how over 100 of the most frequently mutated oncoproteins and tumour suppressor proteins interact with each other. It was presented and distributed at the 2017 American Association for Cancer Research Meeting and is downloadable from the Kinexus website (http://www.kinexus.ca/pdf/OncoNET_Poster.pdf).

viii. BLOG COMMENTARIES

Over the last decade, I have written commentaries on over 300 blogs as part of an outreach effort to inform the broader scientific community on a wide range of issues ranging from career development to genomics to biotechnology. I have only listed those commentaries that appeared primarily at the GenomeWeb website. Unfortunately, these, like all previous commentaries, are no longer accessible at the GenomeWeb site, but mine can be viewed at www.kineticaonline.ca in the Blog Comments section.

ix. MEDIA INTERVIEWS

1. Can We Map the Brain? (21/2/2013). To the Point with Warren Olney. On National Public Radio KCRW. Topic - President Obama wants to do for the human brain what the Human Genome Project did for Genetics. But even scientists backing the idea concede that "mapping the brain" is orders of magnitude more complex. How should it be funded? Is it possible? Would it give scientists powers

nobody wants them to have? Guests: John Markoff: New York Times, @markoff; Terrence Sejnowski: Salk Institute, @sejnowski; Steven Pelech: Kinexus Bioinformatics Corporation; Simon Tripp: Battelle Technology Partnership Practice, @battelle.

xi. EXPERT REPORTS FOR COURT CASES

Over the last year, I have been asked to prepare, expert reports with respect to natural immunity and COVID-19 vaccines for several court and arbitration cases in Canada, South Africa and Ireland. These are usually sworn and notarized documents, and in several cases I have undergone cross-examination in Canadian courts. This is a listing of many of the court cases that I have served in.

1.	COURT FILE NUMBER	210600780
	COURT	COURT OF QUEEN'S BENCH OF ALBERTA
	JUDICIAL CENTRE	LETHBRIDGE
	APPLICANT	HAYLEY NASSICHUK-DEAN
	RESPONDENT	UNIVERSITY OF LETHBRIDGE
2.	COURT FILE NUMBER	T-1694-21
	COURT	FEDERAL COURT OF CANADA (Trial Division)
	APPLICANT	DAVID LAVERGNE-POITRAS
	RESPONDENTS	ATTORNEY GENERAL OF CANADA (Minister of Public Services and Procurement) – and – PMG TECHNOLOGIES INC.

3.	COURT FILE NUMBER	2101-13202
	COURT	COURT OF QUEEN'S BENCH OF ALBERTA
	JUDICIAL CENTRE	CALGARY
	APPLICANTS	DR. ERIC T. PAYNE, DR. JOANNE J. MOSER, DR. DAVID W. L. LOEWEN and DR. GREGORY CHAN
	RESPONDENTS	ALBERTA HEALTH SERVICES, DR. VERNA YIU IN HER CAPACITY AS CHIEF EXECUTIVE OFFICER OF ALBERTA HEALTH SERVICES, DR. JOHN T. CHMELICEK IN HIS CAPACITY AS POST GRADUATE PROGRAM DIRECTOR, DEPARTMENT OF FAMILY MEDICINE, UNIVERSITY OF ALBERTA -and- THE UNIVERSITY OF ALBERTA
4.	COURT FILE NUMBER	CV-21-00670360-0000
	COURT	SUPERIOR COURT OF JUSTICE ONTARIO
	APPLICANTS	SARAH HARJEE, EVAN KRAAYENBRINK, HIBAH AOUN, SARAH LAMB, SAM SABOURIN, JACKIE RAMNAUTH, MARK MCDONOUGH -and- LINDA MCDONOUGH

Plaintiffs

- and -

UNIVERSITY OF GUELPH, JEFFREY WICHTEL, LAURIE ARNOTT, CHARLOTTE YATES, SCOTT WEESE, GLEN PYLE, ANDREW PEREGRINE, DOROTHEE BIENZLE, AMY GREER, DAVID FISMAN, NICK DULEY, JANE OR JOHN DOE JUNIOR SCIENTIST

Defendants

AFFIDAVIT OF DR. PIERRE MAJOR

I, Dr. Pierre Major, of the City of Hamilton, in the Province of Ontario, MAKE OATH AND SAY:

1. I am a medical oncologist and Chair of the Colorectal Cancer Canada Medical Advisory Board at the Hamilton Regional Cancer Center. I am also an Associate Professor of Oncology at McMaster University and a research partner of the Plaintiff, and as such, have knowledge of the matters contained in this Affidavit.

Professional, Academic and Research background

2. I am a specialist in medicine and medical oncology. My research training is in experimental therapeutics. I have extensive publications in both preclinical laboratory work and clinical studies. I have worked as a translational researcher at Harvard and McGill universities. Translational research seeks to produce more meaningful, applicable results that directly benefit human health. The goal of translational research is to translate (move) basic science discoveries more quickly and efficiently into practice.

3. I have worked in clinical developments at Syntax (now Roche) and Miles (now Bayer). I am very conversant with the regulatory requirements for bringing medicines to the clinic to treat patients. In my current position at McMaster University and the Juravinski Cancer Center I conduct translational research to bring new therapies in the area of prostate cancer. I have used viruses to treat cancer (oncolytic viruses). Attached as **Exhibit A** is a copy of my CV.

Research Collaboration on cancer and COVID-19 vaccines with Dr. Bridle

4. I have had productive scientific collaborations with Dr. Bridle on cancer research and COVID-19 research. This is demonstrated by the following six published peer-reviewed scientific papers that we co-authored, attached as **Exhibit B**.
5. My initial collaboration with Dr Bridle was in the area of oncolytic viruses.
6. Dr. Bridle is an ideal and exceptional candidate for my research collaboration because of his scientific expertise in the fields of virology, immunology and cancer biology; research skills as a top tier reviewer; and his publication record. Of major importance is that he has been granted a U.S. patent for his work with oncolytic viruses, a key element for eventual venture capital funding.
7. He is also an expert in animal models of cancer and in immunology.
8. These factors are optimal for quickly and efficiently bringing new therapies to patients.
9. Patients with advanced cancer are at greater risk of severe morbidity and mortality from COVID-19.
10. Beginning in January 2020 I began collaborating with Dr. Bridle on a viral vectored vaccine for COVID-19. We used the same virus we had used for cancer work. We selected nasal vaccination as the preferred route and simplest method of vaccination.

Testing in hamsters and primates showed the vaccine was effective at reducing morbidity and preventing mortality but not preventing infection. This is the shortcoming of all available COVID 19 vaccines: they do not prevent the infection or the spread of infection. We decided to use a different pharmaceutical formulation to address this major shortcoming.

11. Dr. Bridle and I are co-inventors of a COVID-19 vaccine that showed promise in our pre-clinical research. Over the past three years, Dr. Bridle and I have had multiple opportunities to engage in national and international research collaborations in this area.

12. Dr. Bridle is also an ideal collaborator, especially for complex projects that involve multiple labs and multiple institutions, due to his wide-ranging expertise spanning the fields of immunology, virology, and cancer biology. In particular, the research team managed by Dr. Bridle is known for their technical sophistication and the integrity of their results. Dr. Bridle emphasizes the importance of being able to repeat scientific findings and he insists on only reporting results that he is confident represent the biological reality rather than some kind of technical artifact.

13. Dr. Bridle's U.S. patent on the use of viruses for cancer therapy covers many viruses including NDV. ***It is a very noteworthy accomplishment to have been granted a U.S. patent.*** Non-American applicants have a very low success rate in the U.S. where the patent office gives priority review to U.S. applicants and is known to be much more demanding of foreign applicants. This is a strong indication of his excellence and integrity as a scientist.

14. It has always been an honour to work with Dr. Bridle because of his unwavering integrity and scientific precision. Over the years I have also come to appreciate his gregarious personality and collaborative attitude.

Cancer research dependent on third party funding

15. Cancer research is primarily funded by agencies that raise their funds via donations from the public, such as the Canadian Cancer Society, Terry Fox Research Institute, and Cancer Research Society. Cancer research is also funded by the federal government-run Canadian Institutes of Health Research.

16. Funding applications require a substantial amount of work. For example, it typically takes more than 160 hours to write a competitive grant application for the Canadian Institutes of Health Research.

17. Dr. Bridle, in the past, successfully obtained funds from Canadian Cancer Society, Terry Fox Research Institute, Canadian Breast Cancer Foundation, Pet Trust Fund, the Cancer Research Society, and private donations in the past ***due to his reputation as a scientist with integrity.***

Importance of Dr. Bridle's cancer research

18. Dr. Bridle's cancer research has advanced the fundamental understanding of cancer biology. It has also helped propel oncolytic virotherapies into clinical research, including having one of his treatment strategies tested in four human clinical trials. Dr. Bridle has also made substantial contributions to the field of cancer vaccinology. Moreover, through his use of viruses as vectors for cancer therapies, he has also made contributions to a basic understanding of antiviral immune responses.

19. Dr. Bridle's recognition as a leader in these areas of research has also been demonstrated by him being invited to serve on grant review panels for the Canadian Institutes of Health Research (for which he has received multiple honours as a top-tier reviewer and was admitted to their prestigious college of reviewers), Cancer Research Society, and Prostate Cancer Canada.

Harm to Dr. Bridle's reputation

20. I have read the affidavit of Dr. Fisman filed in this Motion. I also have direct knowledge of how Dr. Bridle's cancer and COVID19 research was destroyed by the online and social media reaction of the defendants to the brief radio interview with journalist Alex Pierson on May 28, 2021 which has ruined Dr. Bridle's reputation as a scientist.
21. Dr. Fisman is a medical doctor, not a vaccinologist. He was also a member of the Ontario Science Table and a prominent media commentator on COVID-19.
22. He refers to Dr. Bridle as conveying "misinformation", "distorting scientific evidence", making claims that are "poppycock"; "biologically implausible"; "not data based" and "not evidence based" on COVID19 vaccines. These allegations are false.
23. Dr. Fisman mocking and vilifying Dr. Bridle on social media, with the above phrases, and as a "quack": by referring to and promoting a website that impersonates him with an image of a duck, has damaged Dr. Bridle's impeccable reputation as scientist.
24. A scientist's reputation is essential in obtaining funding for research. One of the core aspects of the review process for a grant application is evaluation of the quality of the researcher.
25. Grant funding, especially in the field of cancer research, is very competitive, with funding success rates often being lass than ten percent. This means that any negative points raised

during the review process are almost certain to cause an application to not be funded. Grant review panels typically include many experts from across Canada. Two or three primary reviewers are usually held responsible for reading a grant application in detail. Typically, they will establish a mean score for the application. Their discussions are done behind closed doors. Importantly, other reviewers contribute equally to the final score, but they have the option of lowering their score relative to what the primary reviewers agreed upon.

26. So, national-level defamation of a scientist's character would be expected to have a substantially negative impact on the potential for their grant applications being funded.

Harm to research on cancer and viral vectored vaccines

27. The damage to Dr. Bridle's reputation has halted his research collaboration on the oncolytic virus and the COVID-19 vaccines with me.

28. I was forced to seek foreign collaboration outside Canada to continue the research. This a loss to Canadian cancer research.

29. The damage to Dr. Bridle's reputation has also tainted and harmed me. For example, the vector virus was withheld by another co-inventor at the University of Guelph who blocked the ability of Dr. Bridle and I to pursue our collaborative research opportunities. This meant that we could not manufacture research-grade stocks to provide our collaborators. Without the ability to demonstrate the feasibility of the research, our potential collaborations were nullified.

30. Moreover, I have been shunned by previous collaborators at the University of Guelph and am forced to find other collaborators. This has delayed my COVID-19 research project for years and voided the funds I expended through Revenue Canada Scientific Exploitation and Development (SRED) tax credit. This is a substantial financial loss to me as a direct

result of the personal attacks on Dr. Bridle's integrity, and in particular, that he is "spreading misinformation".

Irreparable Harm to future funding for cancer research

31. The personal attacks in social media and, in particular, the allegation of "anti-vaxxer" against Dr. Bridle, who is a vaccinologist, has destroyed his reputation with funders.
32. For this reason alone, any funding application submitted by Dr. Bridle will likely be rejected outright. So, to invest many weeks of work into each application would not be a valuable use of time until Dr. Bridle's reputation is cleared.
33. Because of the tarnishing of his reputation, Dr. Bridle and I have had to abandon our many research projects together.
34. Dr. Bridle's unique combined expertise in virology, immunology (with a focus on vaccinology and antiviral immunity), and cancer biology, makes him the perfect candidate to partner with. This is a rare qualification that is being wasted due to the reputational harm.
35. I would like to continue my productive collaborations with Dr. Bridle in the field of cancer immunotherapy, which is a shared passion of ours. The only reason I cannot work with Dr. Bridle is the damage to his reputation. Otherwise, he is the ideal collaborator. As previously stated, Dr. Bridle has a U.S. patent on the use of viruses for cancer therapy. It covers many viruses. Very few Canadian scientists have U.S. patents. This is extraordinarily valuable and rare asset for a collaborator. It exemplifies Dr. Bridle's excellence in his field of expertise.
36. I am deeply disturbed and disappointed beyond description by the inability to collaborate with Dr. Bridle due to no other reason except those allegations, which in my opinion are false and without justification. Personal attacks of this vile nature have no place in

scientific discourse and discussion. It is not in the public interest to have academics and scientists lacking expertise mock, demean and insult a highly qualified expert in his field.

SWORN BEFORE ME by Pierre Major in the City of Hamilton, in the Province of Ontario, on this 29th day of November, 2023, in accordance with O. Reg. 431/20 Administering Oath or DeclarationRemotely

A Commissioner for Taking Oaths
Rocco Galati B.A.,LL.B.,LL.M.

Dr. Pierre Major

This is Exhibit "A" to the Affidavit of
Dr. Pierre Major, sworn before me on
this 29th day of November 2023

A Commissioner for Taking Affidavits
Rocco Galati, , B.A., LL.B., LL.M.

Updated 2021 May 7

Pierre Major

NAME Pierre Major

ADDRESS 699 Concession Street
Hamilton
Canada, L8V 5C2

EDUCATIONAL BACKGROUND

Degrees and Diplomas

1974	MD, Medicine, University of Montreal, Montreal, Canada

Qualifications, Licensures and Certifications

1994	Corporation of Physicians of the Province of Quebec(CSPQ) Certification in Medical Oncology
1988	Active Massachusetts License
1979	FRCPC(Internal Medicine), Royal College of Physicians and Surgeons of Canada
1979	Corporation of Physicians of the Province of Quebec(CSPQ) Certification in Internal Medicine
1978	DES(Engineering Science), University of Montreal, Montreal, Canada
1975	License, Medical Council of Canada

Research Training

1982 - 1983	Assistant Professor, Medicine, Harvard Medical School, Boston
1980 - 1982	Experimental Therapeutics, Medicine & Pharmacology, Harvard Medical School, Boston, Supervisor: Instructor
1978 - 1980	Fellow, Medical Oncology and Pharmacology, Dana Farber Cancer Centre, Harvard Medical School, Boston, United States

1978 - 1980	Fellow, Medicine, Peter Bent Brigham Hospital, Boston, Dana-Farber Cancer Institute, Boston
1978 - 1980	Fellow in Medicine, Harvard Medical School, Boston
1977 - 1978	Fellow, Haematology, University of Montreal, Notre-Dame Hospital

Other Specialized Training

2007 - 2008	Senior Adult Oncology, Mofitt Cancer Center, University of South Florida, Tampa, Florida, United States
1976 - 1977	Resident III in Medicine, University of Montreal, Montreal
1975 - 1976	Resident II in Medicine, Univeersity of Montreal, Montreal
1974 - 1975	Intern in Medicine, University of Montreal

CURRENT STATUS AT MCMASTER

2006 - present	Associate Professor, Oncology, CAWAR, Health Sciences, McMaster University

PROFESSIONAL ORGANIZATIONS

American Society of Clinical Oncology, Member

American Association for Cancer Research, Member

American College of Clinical Pharmacology, Member

American Association for the Advancement of Science, Member

American College of Physicians, Member

Fellow of the Royal College of Physicians of Canada, F.R.C.P., Fellow

EMPLOYMENT HISTORY

University Appointments

2006 - present	Associate Professor, Oncology, CAWAR, Faculty of Health Sciences, McMaster University
2000 - 2006	Associate Professor, Medicine, CAWAR, Faculty of Health Sciences, McMaster University
1999 - 2000	Associate Professor, Medicine, Special, Faculty of Health Sciences, McMaster University

1997 - 1999	Associate Professor, Medicine, Contractually Limited, Faculty of Health Sciences, McMaster University

Academic

1987 - 1996	Adjunct Professor, McGill University, Montreal, Department of Medicine
1983 - 1987	Asst. Professor of Medicine, University Full-time, McGill University, Montreal, McGill Cancer Centre
1983 - 1987	Associate Member, Pharmacology and Therapeutics, McGill University, Montreal
1982 - 1983	Asst. Professor of Medicine, Harvard Medical School
1981 - 1982	Junior Associate in Medicine, Brigham and Women's Hospital, Boston
1980 - 1982	Instructor in Medicine, Harvard Medical School

Administrative

2001 - 2002	Co-Chair, Juravinski Cancer Centre, Disease Site Team Council
1997 - 2001	Chairman, Juravinski Cancer Centre, Hamilton, Ontario, Gastrointestinal (GI) Oncology Group
1992 - 1996	Vice-President, Bayer Inc., Medical & Scientific Affairs, Etobicoke, Ontario
1991 - 1992	Vice-President, Scientific Affairs, Syntex Inc. Mississauga, Ontario
1990	Director, Scientific Affairs, Syntex Inc, Mississauga, Ontario
1988 - 1990	Vice-President, Bio-Research Laboratories, Senneville, Quebec, Clinical Research Division
1987 - 1988	Director of Clinical Pharmacology and Medical Director, Bio-Research Laboratories, Senneville, Quebec

Clinical

1996 - present	Medical Oncologist, Juravinski Cancer Centre, Hamilton, Ontario
1983 - 1998	Assistant Physician, Royal Victoria Hospital, Montreal
1987 - 1990	Affiliate Physician, Montreal General Hospital
1983 - 1987	Assistant Physician, Montreal General Hospital
1982 - 1983	Associate Physician, Brigham Women's Hospital, Boston
1980 - 1983	Clinical Associate in Medicine, Dana-Farber Cancer Institute, Boston

Consulting

2004 - present	Oncology Consultant, Guelph General Hospital
1996 - present	Oncology Consultant, Cambridge Memorial Hospital

1998 - 2000	Consultant Physician, Royal Victoria, Hospital, Montreal

Training

1978 - 1980	Fellow in Medical Oncology and Pharmacology, Harvard Medical School, Boston, Dana Farber Cancer Centre
1978 - 1980	Fellow in Medicine, Dana-Farber Cancer Institute, Boston, Peter Bent Brigham Hospital, Boston
1978 - 1980	Fellow in Medicine, Harvard Medical School, Boston
1977 - 1978	Fellow in Haematology, Notre-Dame Hospital, University of Montreal
1976 - 1977	Resident III in Medicine, Hotel-Dieu Hospital, Montreal
1975 - 1976	Resident II in Medicine, Hotel-Dieu Hospital, Montreal
1974 - 1975	Intern in Medicine, University of Montreal

SCHOLARLY AND PROFESSIONAL ACTIVITIES

Editorial Boards

2006 - present	Colorectal Cancer Association Of Canada, Medical Advisory Board
2011	Chair, Medical Advisory Board
2008 - 2011	Cancer Advocacy Coalition of Canada

Grant & Personnel Committees

1996 - 2003	Grant Review Panel B, Cancer Research Society
1992 - 1995	Chairman, Bayer (Miles) CRC R&D Fund
1986 - 1988	Scientific Committee, FRSQ
1985 - 1987	Medical Advisory Board, Cancer Research Society

Executive Positions

2008 - 2010	Vice President, Medical Staff Association
2006 - 2008	Treasurer, Medical Staff Association

Journal Referee

2005 - present	Cancer

1981 - present	Cancer Research

External Grant Reviews

1998	CRS (10)
1997	CRS (15)
1996	CRS (15)
1987	FCAR (1)
1987	MRC (9)
1987	CRS (11)
1987	FRSQ (8)
1986	MRC (4)
1986	CRS(10)
1985	MRC (5)
1985	CRS (8)
1984	MRC (7)
1983	MRC (3)
1983	FCAR (3)
1983	NRC (3)

Chair

2007 - present	International Data Monitoring Committee, Austria Breast Cancer Research Group
2005 - present	Amgen, Data Monitoring Committee

Other Professional Activities

2008	John Collaci Fund Raiser
2008	Colorectal Cancer Association of Canada, Training of cancer coaches for patients with colorectal cancer
2007	Consultant (10% time allocated) to international pharmaceutical companies including: Review of global development plans, FDA Meeting preparation, Protocol reviews
2001	Guest Speaker at the Multiple Myeloma Peer Support Group – Toronto & District, Summer 2001

2001	Guest Speaker at the 2nd Annual Bernie Faloney Invitational Golf Tournament to support the Colorectal Cancer Association of Canada, Spring, 2001
1999	Advisory Board, Colorectal Cancer, Association of Canada

AREAS OF INTEREST

1. MEDICAL ONCOLOGY

Clinical

1. GASTROINTESTINAL ONCOLOGY, Breast Oncology, Geriatric Oncology

Consulting

1. Data Monitoring Committee, Amgen
2. Austrian Breast and Cancer Research Group

Research

1. cancer vaccine, oncolytic viruses

Teaching

1. medical students, residents rotating through clinics

HONOURS AND AWARDS

1991	Syntex, President's Award for Outstanding Achievement
1986	Montreal General Hospital, Stewart Award
1985	Montreal General Hospital, Stewart Award
1984	Montreal General Hospital, Stewart Award
1983	Montreal General Hospital, Stewart Award
1983	Medical Research Council of Canada, Scholar (1983 - 1987)
1980	Medical Research Council of Canada, Fellowship (1980 - 1983)
1978 - 1980	Canadian Cancer Society, McEachern Fellowship
1978	Canadian Cancer Society, McEachern Fellowship (1978 - 6/1980)
1971	Health and Welfare Canada, Research Scholarship

1971	Health & Welfare Canada, Research Scholarship
1971	Health & Welfare Canada, Health & Welfare Canada Research Scholarship
1970	Medical Research Council of Canada, Summer Undergraduate Research Scholarship

COURSES TAUGHT

Undergraduate Teaching

Physician Assistant Education Program

2012 Jul - 2019 Jun Supervisor, Elective, Interviewing, Examination and Reasoning, half-day (12)

Undergraduate Medical

2000 Jul - 2016 Jun Examiner, Observed Structured Clinical Examination, occasion (5)

2010 Jul - 2016 Jun Supervisor, Block Elective (Clinical/Reading/Research), week (22)

2012 Jul - 2014 Jun Supervisor, Elective, Visiting Student, week per student (10)

2006 Jul - 2011 Jun Supervisor, Horizontal Elective, week per student (4)

2007 Jul - 2008 Jun Assessor, Admissions, Multiple Mini Interview, weekend (1)

2007 Jul - 2008 Jun Reader, Admissions, Autobiographical Submission, year (1)

1999 Jul - 2001 Jun Student Advisor, student per year (2)

Undergraduate Medical Clerkship

2013 Jul - 2020 Jun Supervisor, Medical Subspecialties, rotation (8)

Postgraduate Teaching

Family Medicine and its subspecialties

2013 Jul - 2017 Jun Supervisor, Outpatient, clinic (22)

Internal Medicine and its subspecialties

2007 Jul - 2009 Jun Examiner, Observed Structured Clinical Examination, half-day (2)

2003 Jul - 2004 Jun Presenter, Rounds, occasion (12)

2003 Jul - 2004 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, half-day (48)

2003 Jul - 2004 Jun Supervisor, Clinical, Inpatient, day (10)

1999 Jul - 2000 Jun Advisor/Mentor, resident per year (1)

1999 Jul - 2000 Jun Presenter, Academic Half-Day, occasion (3)

1999 Jul - 2000 Jun Presenter, Clinical Teaching Unit, occasion (1)

1999 Jul - 2000 Jun Presenter, Journal Club, occasion (1)

1999 Jul - 2000 Jun Supervisor, Block Elective, half-day (12)

Oncology and its subspecialties

2014 Jul - 2020 Jun Supervisor, Clinical, Inpatient, (4 weeks), month (4 weeks) (5)

2014 Jul - 2020 Jun Supervisor, Outpatient, clinic (1042)

2014 Jul - 2018 Jun Supervisor Block Elective, week (6)

2016 Jul - 2017 Jun Presenter, Academic Half Day/Core Curriculum, presentation (1)

2012 Jul - 2014 Jun Presenter, Academic Half-Day, occasion (2)

2012 Jul - 2014 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, half-day (204)

2012 Jul - 2014 Jun Supervisor, Clinical, Inpatient, day (62)

2006 Jul - 2014 Jun Supervisor, Block Elective, half-day (178)

2012 Jul - 2013 Jun Supervisor, Research, Laboratory-based, week (104)

2011 Jul - 2012 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, 131 half-days x 16 residents (131)

2010 Jul - 2011 Jun Supervisor, Clinical, Inpatient, 17 days
Jayson Potts/Laura Harild, December 13 - 23
Rachel VanderMeer, July 1 - 9, 2010 (17)

2010 Jul - 2011 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, 70 half-days
Maria Bagovich, May 16 - 19, 2011
Jason Yu, April 11 - May 4, 2011
Jason Cheung, April 1 - May 1, 2011
Arthur Lau, March 1 - 31, 2011
Aisling O'Meara, February 1 - 28, 2011
Jayson Potts, September 1 - October 31, 2010
Amin Kay, August 24 - September 19, 2010
Karen Lumsden, July 27 - August 23, 2010
Mahraz Anjum, July 5 - 25, 2010
Elena Elimova, July 2 - August 31, 2010
Brandon Meyers, July 1 - August 31, 2010 (70)

2009 Jul - 2010 Jun Supervisor, Clinical, Inpatient, 14 days
Brandon Meyers, September 2 - 8, 2009
Brian Lee, September 2 - 8, 2009
Asma Ali, August 24 - August 31, 2009 (14)

2009 Jul - 2010 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, 111 half-days
Humaid Al-Shamsi
Puja Sahni
Bryan Lee
Kosta Ioannou
Vikaash Kumar
Sadiya Kukaswadia
Raheb Elzuway
Abir Nawara
Dawn Armstrong
Sergey Pozdnyako
Dean Raso
Ravi Ramjeesingh
Blair Leonard
Aalok Kumar
Miranda Schell (111)

2008 Jul - 2009 Jun Presenter, Academic Half-Day, 2 occasions
Metastatic Colorectal Cancer, December 17, 2008
Esophageal and Gastric Cancer, November 19, 2008 (2)

2008 Jul - 2009 Jun Supervisor, Clinical, Elective (Block), 73 half-day clinics
Brandon Meyers, May 1 - 17, 2009
Rachel VanderMeer, May 8 - 31, 2009
Katalin Koller, April 1 - 30, 2009
Kimmen Quan, April 1 - 30, 2009
Lindsay Crabbe, March 1 - 31, 2009
N. Popat, March - April 2009
Waseem Sharieff, February 2 - March 1, 2009
Adrienne Penderell, February 2 - March 1, 2009
Puja Kumar, January 1 - February 1, 2009
A. Lau, January 2009
M. Mathivanan, September - October 2008 (73)

2008 Jul - 2009 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, 99 half day clinics
Sabrina Allegro, May 1 - June 30, 2009
Abdullah Al-Zahrani, Oct 1 - Nov 30, 2008, Feb 2 - March 31, 2009
Sara Rask, February - March 2009
Sayeh Lavasani, December 1 - February 1, 2009
Khalid Al-Saleh, November 3 - January 1, 2009
Asma Ali, July 1 - November 2, 2008
Radhika Yelamanchilli, July 1 - September 20, 2008 (99)

2008 Jul - 2009 Jun Supervisor, Clinical, Inpatient, 20 days
Khalid Al-Saleh, March 23 - April 3, 2009
Rania Lingas, July 28 - August 8, 2008
Vikash Kumar, July 28 - August 8, 2008 (20)

2007 Jul - 2008 Jun Presenter, Academic Half-Day, 1 occasion
GI - Review of Anal and Rectal Cancer, March 12, 2008 (1)

2007 Jul - 2008 Jun Presenter, Regional Oncology Rounds, 2 occasions
Boen Markers in Cancer Metastatic to Bone, February 7, 2008
Geriatric Oncology, June 7, 2007 (2)

2007 Jul - 2008 Jun Supervisor, Clinical, Inpatient, 20 days
Aswaq Alolayan, January 28 - February 8, 2008
Radhika Yelamanchilli, August 13 - 26, 2007
V. Pavlova, August 13 - 26, 2007 (20)

2007 Jul - 2008 Jun Supervisor, Clinical, Out-patient/Ambulatory Care, 100 half day clinics
Sara Taylor, April 8 - May 7, 2008
Rania Lingas, January 2 - March 2, 2008
Sara Kuruvilla, November 1 - January 1, 2008
Sayeh Lavasani, September 4 - October 31, 2007
Ashwaq Alolayan, July 1 - September 3, 2007 (100)

2007 Jul - 2008 Jun Supervisor, Clinical, Elective (Block) 64 half-day clinics
Khuloud Nuri, June 2 - 30, 2008
Ioanna Papoutsi, May 1 - 31, 2008
Daniela Leto, April 1- 30, 2008
Vincent Tam, April 2008
I. MacDougall, March - April 2008
Bryan Lee, February 13 - March 10, 2008
K. D'Silva, January - February 2008
F. Bacchus, November - December 2007
Vikaash Kumar, September 4 - 30, 2007
Sue Richter, September 4 - 14, 2007 (64)

2005 Jul - 2007 Jun Examiner, Observed Structured Clinical Examination, half-day (2)

2006 Jul - 2007 Jun Presenter, Rounds, occasion (1)

2006 Jul - 2007 Jun Reader, Admissions, candidate (60)

2006 Jul - 2007 Jun Resource Person, Clinical Teaching Unit, occasion (4)

Other

Continuing Education

2005 Jul - 2006 Jun Speaker, occasion (5)

Additional Educational Contributions

McMaster teaching outside FHS

1986 - 1987	Pharmacology 549-221-M. Pharmacology of anti-tumour agents. McGill Medical School curriculum. (1)
1985 - 1986	Pharmacology 549-221-M. Pharmacolgoy of anti-tumour agents. McGill Medical School curriculum. (1)
1985 - 1986	Pharmacology 549-7028 (Graduate Course). Biochemical Pharmacology of anti-tumour drugs. Lectures: 10 hours Seminars: 20 hours McGill Medical School curriculum. (1)
1984 - 1985	Pharmacology 549-221-M. Pharmacologyof anti-tumour agents. McGill Medical School curriculum. (1)

SUPERVISORSHIPS

Supervisory Committees

Medical Sciences

2019 Jul - 2020 Jun Member, Supervisory, Committee, MSc, student per year (1)

RESEARCH FUNDING

Grants (Primary Investigator's name is the first name listed)

2018 Sep - 2021 Sep	Damu Tang, M. Bonert, A. Kapoor, P. Major, N. Seidah, G. Werstuck, PCSK9, a novel contributor to the development of castration resistant prostate cancer, Grant, Canadian Institute of Health Research, Research - New Project, $57,574.00
2003 Jan - present	Major, P, A randomized, double-blind, placebo-controlled, phase III study in patients with metastatic adenocarcinoma of the colon or rectum who are receiving first-line chemotherapy with oxaliplatin/5-flkuorourcil/leucovorin and PTK787/ZK 222584 or placebo, Grant, Novartis Oncology US, Clinical Trial, $350,000.00
2010 - 2014	Foley, R, Major, P, Fradet, Y, Dendritic Cell Vaccine for Prostate Cancer, Grant, OICR, Research - New Project, $484,000.00

2006 - 2010	Foely, R, Major, P, Fradet, Y, Dendritic Cell Vaccine for Prostate Cancer, Grant, CANVAC, Research - New Project, $300,000.00
2003 Jan - 2007	Major, P, A randomized, double-blind, placebo-controlled, phase III study of oxaliplatin/5-fluorouracil/leucovorin with PTK 787/ZK 222584 or placebo in patients with previously treated metastatic adenocarcinoma of the colon or rectum, Grant, Novartis Oncology US, Clinical Trial, $125,000.00
2001 Jan - 2006 Dec	Major, P, Phase II contract for early phase with emphasis on phase II studies awarded to Princess Margaret/Hamilton Regional Cancer Centre/London Regional Cancer Centre consortium., Grant, NCI-US, Clinical Trial, $5,500,000.00
2000 Jan - 2003 Dec	Major, P, The pharmacokinetics and pharmacodynamics of Zoledronic Acid in cancer patients with varying degrees of renal function, Grant, Novartis Oncology US, Clinical Trial, $104,256.00
2000 Jan - 2001 Dec	Major, P, R.Cook, Assessing the Therapeutic Effect of Aredia in Randomized Trials of Patients with Breast Cancer Metastatic to Bone. Request for funds to develop a mathematical model describing the natural history of breast cancer metastatic to bone and to analyse the effect of Aredia on the course of the disease using recently developed statistical techniques for the analysis of recurrent events, Grant, Novartis, Clinical Trial, $17,000.00
2000 Jan - 2001 Dec	Major, P, Extension Trial . An open label multicentre clinical study to evaluate the long term safety of intravenous Zometa (Zoledronate)8 mgm. in patients with metastatic bone lesions due to breast cancer or multiple myeloma, Grant, Novartis Oncology US, Clinical Trial, $24,900.00
2000 Jan - 2000 Dec	Major, P, A. Arnold, E. Chouinard,H. Hirte,R. Tozer, Extension-Zoledronate l0EA A randomized, double-blind, multicentre, comparative trial of iv Zoledronate (4mg or 8 mg) versus iv Aredia© (90mg), as an adjunct to standard therapies, in the treatment of multiple myeloma and breast cancer patients with cancer-related bone lesions, Grant, Novartis Oncology US, Clinical Trial, $58,000.00
2000 Jan - 2000 Dec	Major, P, J. Sathya, M. Patel, J Wu, H. Lukka, T. Corbett, A. Neville, A randomized double-blind placebo controlled phase III trial evaluating zoledronate plus standard therapy vs placebo & standard therapy in patients with recurrent carcinoma of the prostate who are asymptomatic with castrate levels of testosterone and have rising PSA levels without radiologically-evident metastatic disease, Grant, Novartis Oncology US, Clinical Trial, $180,000.00
1999 Jan - 2000 Dec	Major, P, E. Chouinard, P. McCulloch, A. Figueredo, SCH 766336: A Phase II Randomized, Open-Label Study of SCH 66336 and an Active Reference Agent Gemcitabine in Patients with Metastatic Adenocarcinoma of the Pancreas, Grant, Schering-Plough Research Institute, Clinical Trial, $10,000.00
1999 Jan - 2000 Dec	Major, P, E. Chouinard, P. McCulloch, A. Figueredo, SCH 766336: A Phase II Randomized, Open-Label Study of SCH 66336 and an Active Reference Agent Gemcitabine in Patients with Metastatic Adenocarcinoma of the Pancreas, Grant, Schering-Plough Research Institute, Clinical Trial, $10,000.00

1999 Jan - 2000 Dec	Major, P, H. Hirte, E. Chouinard, R. Tozer, A Arnold, D. Marcellus, R.Meyer, A. Benger, R. Foley, An open label, randomized, multicenter clinical study to investigate the efficacy and tolerability of intravenous Zometa (Zoledronate) 40 mg in patients with metastatic bone lesions due to breast cancer or multiple myeloma, Grant, Novartis Oncology US, Clinical Trial, $46,400.00
1998 Jan - 2000 Dec	Major, P, P. McCulloch, A. Figueredo, E. Chouinard, A double-blind, placebo-controlled, minimized phase III study comparing Marimistat to Placebo as adjuvant therapy in patients with resectable pancreatic cancer, Grant, British Biotech, Clinical Trial, $10,000.00
1998 Jan - 2000 Dec	Major, P, H. Hirte, R. Tozer, A randomized, double-blind, multicentre, comparative trial of Zoledronate (4 and 8 mgm. i.v.) versus Aredia (90 mgm. i.v.) as an adjunct to chemotherapy, in the treatment of multiple myeloma and breast cancer patients with osteolytic lesions, Grant, Novartis, Clinical Trial, $50,000.00
1997 Jan - 1999 Dec	Major, P, H. Hirte, R. Tozer, An open label, randomized multicentre evaluation of the safety and tolerability of Pamidronate (90mgm) administered as an intravenous infusion over 4, 2 or 1 hour., Grant, INT, Clinical Trial, $60,000.00
1997 Jan - 1999 Dec	Major, P, H. Hirte, L. Reyno, R. Tozer, A randomized double-blind study of two doses of Zoledronate and Aredia 90 mgm. in the treatment of tumour induced hypercalcemia., Grant, Novartis, Clinical Trial, $60,000.00
1996 Jan - 1998 Dec	Hirte, H, Major, P (Local Investigator), Phase I Trial of the Matrix Metallo Proteinase Inhibitor BAY 12-9566, Grant, NCIC Clinical Trial IND Group, Clinical Trial, $38,000.00
1985 Jan - 1989 Dec	Dion, A, Major, P, Human epithelial membrane antigens, Grant, NIH, Research - New Project, $336,000.00
1987 Jan - 1988 Dec	Major, P, G. Prud'Homme, L. Rosenthall, Monoclonal antibodies for diagnosis and therapy of human breast cancer, Grant, NCI, Research - New Project, $39,000.00
1987 Jan - 1988 Dec	Major, P, Regulation of expression of breast tumour markers, Grant, CRS, Research - New Project, $37,000.00
1985 Jan - 1988 Dec	Major, P, D. Ecobichon, K. Ogilvie, Clinical pharmacology of novel antivirals, Grant, MRC, Research - New Project, $234,000.00
1985 Jan - 1987 Dec	Major, P, Group grant for developing new approaches to treating breast cancer, Grant, FRSQ, Research - New Project, $119,000.00
1985 Jan - 1987 Dec	Major, P, G. Prud'Homme, L. Rosenthall, Monclonal antibodies for diagnosis and therapy of human breast cancer, Grant, NCI, Research - New Project, $96,000.00
1985 Jan - 1985 Dec	Major, P, G. Prud'Homme, L. Rosenthall, Rat model of breast cancer, Grant, CRS, Research - New Project, $20,000.00
1983 Jan - 1985 Dec	Major, P, Monclonal antibodies for diagnosis and therapy of human breast cancer, Grant, NCI, Research - New Project, $76,000.00
1983 Jan - 1984 Dec	Major, P, Monoclonal antibodies for diagnosis and therapy of human breast cancer, Grant, CRS, Research - New Project, $10,000.00

1983 Jan - 1984 Dec	Major, P, Monoclonal antibodies for diagnosis and therapy of human breast cancer, Grant, FRSQ, Research - New Project, $20,000.00
1981 Jan - 1984 Dec	Kufe, D, Major, P, Molecular modulations of ARA-C therapy in man, Grant, NIH, Research - New Project, $211,000.00
1982 Jan - 1983 Dec	Major, P, Biomedical research support grant - Monoclonal antibodies for diagnosis and therapy of breast cancer, Grant, NIH, Research - New Project, $15,000.00
1981 Jan - 1983 Dec	Kufe, D, Major, P, Molecular enhancement of Ara-A therapy, Grant, ACS, Research - New Project, $191,000.00
1980 Jan - 1981 Dec	Major, P, Pharmacology of ARA-C (Biomedical research grant), Grant, NIH, Research - New Project, $12,000.00

PATENTS AND COPYRIGHTS

2003 Treating Carcinoid Neoplasms with Therapeutic Viruses, Robert Lorence and Pierre Major

LIFETIME PUBLICATIONS (Principal Author is the first name on each of the entries below)

Peer Reviewed Contributions to Books

UNIVERSITY OF GUELPH, JEFFREY WICHTEL, LAURIE ARNOTT, CHARLOTTE YATES, SCOTT WEESE, GLEN PYLE, ANDREW PEREGRINE, DOROTHEE BIENZLE, AMY GREER, DAVID FISMAN, NICK DULEY, JANE OR JOHN DOE JUNIOR SCIENTIST

Defendants

AFFIDAVIT OF DR. NIEL KARROW

I, Dr. Niel Karrow, of the City of Guelph, in the Country of Canada, MAKE OATH AND SAY:

1. I am a professor of Immunotoxicology and Immunogenetics at the University of Guelph and an academic and professional colleague of Dr. Bridle, and as such, have knowledge of the matters contained in this Affidavit.

Professional, Academic and Research Association with Dr. Bridle

2. I am a senior immunologist and have collaborated for over 23 years with Dr. Bridle at the University of Guelph. Attached as **Exhibit A** is my CV.
3. Drs. Bridle, Bonnie Mallard, Shayan Sharif, and I, are the four (4) senior immunologists at the University of Guelph. This means that we have advanced training and expertise in immunology. Of the four of us, Dr. Bridle is the most knowledgeable about the immunological mechanisms by which a natural immune response is elicited by the SARS-CoV-2, the causative agent of COVID-19, and the immunity afforded by COVID-19

vaccines due to his combined qualifications, insights and critical thinking skills, in, not just immunology, but also vaccinology (a sub-discipline of immunology) and virology.

4. In addition to working closely with Dr. Bridle on campus, all three of us have collaborated on research and published peer-reviewed publications with Dr. Bridle in immunology, including on COVID-19.

5. For example, Dr. Bridle published five lay articles on the topic of COVID-19 in the academic publication known as "*The Conversation*", with Dr. Sharif, one of which was also published in French, attached as **Exhibit B** to this affidavit. Dr. Sharif has also co-authored six published peer-reviewed scientific papers with Dr. Bridle over the past three years, on the topics of antiviral immune responses and avian influenza, including one paper focused on a vaccine against avian influenza. Citations of the peer-reviewed papers are attached as **Exhibit C** to this affidavit.

6. I have published four (4) peer-reviewed publications with Dr. Bridle. Attached as **Exhibit D** is a list of citations of our peer-reviewed papers.

7. Dr. Mallard has ten peer-reviewed publications with Dr. Bridle. She is providing her own affidavit evidence in this Motion.

8. In recognition of the fact that Dr. Bridle is the *most* qualified immunologist on the topic of COVID-19 at the University of Guelph he was recruited to give a lecture on the subject in the new course "Pandemics" designated as UNIV*2020.

9. I can confidently speak on behalf of all three of the University's senior immunologists that Dr. Bridle is an extremely reliable, meticulous, and excellent researcher. He has received multiple top-tier honours in recognition of this fact by the Canadian Institutes of Health Research, and is a member of their prestigious college of reviewers, and has served by

invitation on their Virology and Viral Pathogenesis and Cancer Biology and Therapeutics grant review panels.

10. I know Dr. Bridle to be a person of unwavering integrity and conviction. In all the 23 years I have worked with him I know Dr. Bridle has never provided wrong or misleading information, let alone deliberately disseminated false information in his field of expertise.

11. On a personal level I know Dr. Bridle is a dedicated Christian with excellent character, and a strong moral imperative to speak the truth, even if it is contrary to the prevalent discourse.

"Misinformation" allegations and smear campaign against Dr. Bridle

12. I have read the affidavit of Dr. Fisman, filed in the within motion and listened to the Global "On Point" radio interview of Dr. Bridle on May 27, 2021, with journalist Alex Pierson (hereinafter "On Point interview").

13. On May 30, 2021, I was copied on an email from Dr. Bridle to Dr. Glen Pyle, titled "smear campaign", attached as **Exhibit E**. (Dr. Pyle is professor of biophysics and biomedical sciences, at the University of Guelph.) The email included a screenshot of Dr. Pyle's posts along with Dr. Fisman's social media post on Twitter, dated May 29, 2021, at 5:40 PM after the On Point radio interview, Dr. Fisman stated:

> "I've had questions over the past 48h about vaccine safety concerns aired Dr Bryam Bridle at @UofGuelphOAC in some recent interviews. I don't know Dr Bridle but he's a legit immunologist. Some claims, however, are not data based, and are answered here: byrambridle.com"

14. Dr. Bridle's email to Dr. Pyle stated:

> "Glen,
> I do not use social media. So, yes, it has been happening without my knowledge. If I ever have a problem with someone's science on campus, I take it up with them. This would have been the respectful thing to do. The major problem here was the fact that you did not condemn an egregious act against a colleague when you had the opportunity.

Sincerely,
Byram"

15. In his May 29, 2021, post, above, Dr. Fisman references and promotes a website set up to discredit Dr. Bridle. I viewed the website that bore Dr. Bridle's name. It gives the false impression it is his website. There is an image of a duck and comments that demean, mock, and belittle Dr. Bridle that imply to the reader that he is a "quack". I know the fact that a website was set up only to impersonate Dr. Bridle to discredit him as a viral immunologist terrified him and caused him anxiety. On May 29, 2021, I received an email from Dr. Bridle at 11:17 PM, attached as **Exhibit F** after the above radio interview aired and Dr. Fisman's tweet, stating:

> "Hi all,
> I have to admit that I am starting to get a bit scared. A website was made within the last 48 hours to discredit me…
> http://byrambridle.com/
> This has gotten very ugly very fast.
> Sincerely,
> Byram"

16. On May 31, 2021, I was copied on an email from Dr. Bridle to Dr. Scott Weese titled "misinformation", attached as **Exhibit G**. (Dr. Weese is a professor of pathobiology and a veterinary internist at the University of Guelph). The email included a screenshot of Dr. Weese's Twitter post of May 30, 2021, at 11:49 AM replying to Dr. Pyle and Dr. Fisman.

17. Dr. Weese's post was:

> "Its's tough but misinformation has to be challenged. More misinformation and confusion during a pandemic are dangerous and causing harm.

18. Dr. Bridle's email to Dr. Weese states, in part:

> "Like it or not, I'm not going to conform to your way of thinking about the pandemic and I have scientifically valid reasons for it. I am allowed to be an independent critical thinker."

19. Dr. Pyle and Dr. Weese's objections to Dr. Bridle expressing countervailing views to the government narrative were apparent. Their vehement opposition to Dr. Bridle's expressions was publicly announced in an Open letter they wrote with two other University of Guelph faculty members dated July 6, 2021.

Dr. Fisman's claims of Dr. Bridle spreading "misinformation" & "disinformation" are false

20. The claims made by Dr. Fisman, in his affidavit, that Dr. Bridle misrepresented the science regarding COVID-19 vaccines, and are not supported by evidence in scientific literature, are false. Therefore, the assumption that Dr. Bridle's statements are "dangerous" or "caused harm" is not supported by any evidence, and, is also false.

21. Although Dr. Fisman did not identify which of Dr. Bridle's claims were misinformed, based on my knowledge of immunology and peer-reviewed publications, all the points made by Dr. Bridle during the On Point interview ***are*** supported by scientific evidence and, in fact, have been borne out to be verified to be true:

    a. The vaccine components do not stay in the arm, they biodistributed throughout the body.[1]

    b. Spike protein has been detected in heart tissue and has been detected in blood and exosomes, which can distribute throughout the body and can be shed in bodily fluids.[2]

[1] Ogata, A.F., Cheng, C.A., Desjardins, M., Senussi, Y., Sherman, A.C., *et al.* (2022) Circulating Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) vaccine antigen detected in the plasma of mRNA-1273 vaccine recipients. Clin Infect Dis. 74(4):715-718. doi:10.1093/cid/ciab465

[2] Di, J., Du, Z., Wu, K., Jin, S., Wang, X., Li, T., Xu, Y. (2022) Biodistribution and non-linear gene expression of mRNA LNPs affected by delivery route and particle size. Pharm Res. 39(1):105-114. doi: 10.1007/s11095-022-03166-5

c. Vaccine mRNA and antibodies have been detected in mother's milk which poses risk to nursing infants.[3]

d. Concern about targeting reproductive tissues has also been confirmed.[4]

e. The COVID-19 vaccines also contribute to increased risk of blood clotting, stroke, neurological complications, anaphylaxis, myopericarditis and heart attack.[5]

22. Dr. Bridle had the above insights in May 2021 due to his expertise. This is now indisputably evident in the most current scientific data.

23. I had the same genuine concerns as Dr. Bridle about the production, testing, efficacy and safety of the COVID-19 genetic vaccines, which Dr. Fisman labels as "misinformation" and "disinformation". I know Dr. Bonnie Mallard, the most senior immunologist at the university, also had the same concerns. On July 6, 2021, I sent an email to five of my personal acquaintance co-faculty members at the University, who are not immunologists, but signed the letter drafted by Drs. Weese and Pyle and two others. I set out the scientific rational which supported Dr. Byram's answers in the On Point interview, attached as **Exhibit H**. My email states, in part:

> "Byram is an expert in his field, and I share many of his concerns regarding vaccinating children, and also pregnant women.
> ….
> It is surprising to me that someone like Byram, who is expressing concerns about vaccine safety is shut down after providing evidence of their potential risk, when it is supposed to be the vaccine makers who should be providing the evidence of their safety!"

---

[3] Yeo, K.T., Chia, W.N., Tan, C.W., Ong, C., Yeo, J.G., *et al.* (2022) Neutralizing activity and SARS-CoV-2 vaccine mRNA persistence in serum and breastmilk after BNT162b2 vaccination in lactating women. Front Immunol. 12:783975. doi:10.3389/fimmu.2021.783975

J Infect Public Health. 2023 May;16(5):697-704. doi: 10.1016/j.jiph.2023.02.019. Epub 2023 Mar 2. PMID: 36934644; PMCID: PMC9979695.

[5] "Inflammation after COVID19 Vaccination: An Endomyocardial Biopsy-Proven Case Series" *International Journal of Molecular Sciences*, 2022, 23, 6940 http://doi.org/10.3390/ijms23136940

24. With respect, in my opinion, Dr. Fisman does not have the scientific expertise required to understand Dr. Bridle's assertions of the science. His expertise as an epidemiologist is in the study of the distribution and determinants of disease. His work focuses on mathematical modelling, not on SARS-CoV-2 immunity or long-term safety of COVID-19 vaccines.
25. Dr. Fisman also asserts in his affidavit that Dr. Bridle's scientific assertions are "misinformation" because they "were contrary to the overwhelming majority of scientific opinion". This itself is a questionable statement. But, even if true, expressing dissenting opinions was never a problem for scientists – questioning and challenging conventional thinking is what we do as scientists daily. This is not a basis to accuse a scientist who offers his opinions in his area of expertise based on peer-reviewed science, of "spreading misinformation" and "disinformation".
26. I can confirm that Dr. Bridle's scientific assertions, whether contrary to the opinion of other scientists, are neither wrong (misinformation), nor deliberately falsified (disinformation). I know that such a claim by a scientist is tantamount to an allegation of fraud. It can destroy the academic and research career of a scientist.
27. With respect to his speech mannerisms during the interview, I know Dr. Bridle has Tourette Syndrome. He exhibits tics and stutters. This is apparent and exacerbated when he is stressed. I know he does not like public speaking and would not willingly participate in public events or media interviews unless he was 100% certain of his message and concerns.

Background and context at the University of Guelph

28. Since March 2020, to the present, given our respective interest and expertise in immunology, Dr. Bridle, Dr. Mallard, and I meet weekly to discuss the emerging science and data related to COVID-19. Dr. Bridle followed that scientific literature closely due to

his expertise in both immunology and virology. I have personal knowledge of his untiring efforts to remain apprised of all COVID-19 related publications in his field of expertise.

29. On March 3, 5, 16, and 23, 2021, I co-authored several “Open Letters” to Public Health and the Premier of Ontario to warn against mandating experimental “vaccines" to the public at large setting out the safety concerns, which Dr. Fisman claims are “misinformation”, attached as **Exhibit I.**

30. The same scientific information referenced in the open letters were also discussed in a meeting the three of us had with the Vice-President, Academics, Dr. Cate Dewey, at the University of Guelph on March 11, 2021. Dr. Dewey stated our concerns were valid and no member of the university should be coerced or pressured to take a COVID19 vaccine. During the meeting Dr. Dewey also said to us that she would not support a mandate.

31. Dr. Dewey appointed me, and Drs. Mallard and Bridle, as points of contact for student or staff who experienced pressure to take a COVID-19 vaccine. As a result, I was contacted confidentially by students and faculty and became aware of increasing pressure on campus regarding COVID-19 vaccines within the university community and faculty who disapproved of any criticism of Public Health policies.

32. Because Dr. Bridle is the most authoritative of all the senior immunologists at the University, he was sought after for media interviews and public speaking engagements to provide information and insights on SARS-CoV-2 and COVID-19 vaccines. He gained a reputation as a scientist who provided plain, easy-to-understand and truthful answers to complex questions. His expertise garnered both national and international media interviews.

33. However, Dr. Weese disliked Dr. Bridle's media appearances and pushed for censorship of his expressions on COVID-19 with the University administration. On April 15, 2021, Drs. Mallard and Bridle informed me and I believe they were "warned" by Dr. Weese to stop making statements contrary to public health at a Departmental meeting. News travels fast within the university and it was no secret that Dr. Weese disliked the public attention Dr. Bridle's public speaking and media interviews garnered.
34. Dr. Fisman added fuel to the fire here with his May 29th, 2021, post. Dr. Fisman's allegation against Dr. Bridle renewed Dr. Weese's campaign to discredit and censor Dr. Bridle.

On-line personal harassment is not scientific debate or disagreement.

35. I do not have a Twitter account and I am not on social media. I became aware of Dr. Fisman's social media posts when I received emails with screenshots from Dr. Bridle or immunology students and research assistants who fear reprisals from Drs. Weese and Pyle to disclose their name. This is how I learned that Dr. Weese was posting comments about Dr. Bridle that had nothing to do with science.
36. On June 24th, 2021, Dr. Bridle sent an email including tweets for Dr. Weese and Dr. Fisman. The email is attached as **Exhibit J**. Dr. Weese made disparaging references to Dr. Bridle, "spreading manure", after Dr. Bridle published a scientific paper on COVID-19 vaccines and children**.** This post is improper for an academic colleague. It is insulting and abusive.
37. In another, Dr. Weese, re-tweeted an earlier post by Dr. Fisman which had nothing to do with science, referring to Dr. Bridle as an "anti-vaxxer", "white supremist", "neo-Nazi". With Dr. Fisman's post, dated May 10, 2021, retweeted by Dr. Weese on November 10, 2021, with a link that goes directly to Dr. Bridle's photo, name and where he works.

38. These posts vilify and malign Dr. Bridle's character and are not about science.

39. I was also the subject of Dr. Weese's Tweet hate after the publication of my 2021 paper, which I co-authored with Dr. Bridle and others on "Maternal COVID-19 Vaccination and Its Potential Impact on Fetal and Neonatal Development".

40. I could not respond or defend myself as I am not on Twitter. Drs. Weese and Fisman know that I am not on Twitter. They also know Dr. Bridle is not on Twitter. It is unprofessional and unscholarly for academics to post personal insults and hateful comments about an academic colleague. On September 8, 2021, I requested the University to intervene and mediate or curtail the abusive posts by Drs. Weese and Pyle by email, attached as **Exhibit K**, which in part states:

> "I came across a Tweet that I find very disturbing (attached). I don't know Weese, nor do I care to, but his tweets are very immature and unprofessional. I believe as colleagues, we should be able to listen to and respect each other, and hopefully learn together. …I am embarrassed by Weese's childish behaviour, and I am ashamed to be affiliated with the same university that he attends. Since when did we learn to stoop so low?...If he disagrees with Bridle, then why doesn't he just sit down with him and discuss his concerns? Why the public slandering? This kind of caddy behaviour makes us all look bad and it says so much more about Weese's character than what Bridle stands for. Moving forward I think a mediator should be considered. In the short-term please show how curtail these Tweets."

41. The University did nothing to stop or curtail the personal nature of Dr. Weese's Tweets and re-tweeting of Dr. Fisman against Dr. Bridle.

42. I know Dr. Bridle invited scientific discussions and debates in person, as is the practice in academia by email until he was prohibited by the Dean. The June 24th, 2021 email is one example under Exhibit J above.

43. Dr. Bridle's request for a scientific conversation was not accepted by Drs. Fisman, Pyle or Weese because I believe it was not their intention to discuss or debate, but rather silence Dr. Bridle.

Harms for alleging Dr. Bridle is "an immunologist spreading misinformation"

44. After qualifications, reputation of a scientist is the most valuable asset.

45. Dr. Bridle being referred to spreading "misinformation" or "making claims that are not data or evidence-based" by Dr. Fisman, together with Dr. Weese, referring to him as "neo-Nazi" and "white supremist" has destroyed Dr. Bridle's reputation.

46. It has instilled fear amongst Dr. Bridle's university colleagues and students that they too will be subject to malicious and personal attack on social media for expressing scientific views that are countervailing to the dominant government discourse. It has set a deep chill at our university.

47. The website "byrambridle.com" is clearly a smear campaign against Dr. Bridle. Dr. Fisman's reference to it is underhanded for an academic.

48. Allegations of "misinformation" about vaccines and the derogatory term "anti-vaxxer" for a vaccinologist are fatal to an academic and research career. As immunologists, we advocate for effective and safe vaccines as an important tool to control endemic diseases and prevent emerging diseases. These labels alone immediately result in lost credibility by the immunology community and research funding agencies.

49. Reputation impacts students. It is difficult to recruit and retain immunology graduate students without a solid reputation. I know Dr. Bridle lost two graduate students because they were also adversely affected by the attack against him and feared the disclosure of their names. Without graduate students, it is extremely difficult to convince granting agencies that you have the ability to train highly qualified personnel. This is one criterion used to assess research grant applications.

50. Reputation impacts research funding. Consequently, Dr. Bridle's funding has come to an end, and he will have a very difficult time soliciting funds because "misinformation" and "disinformation" labels by Dr. Fisman, a former member of the Ontario Science Table, will carry weight. It will also be very difficult to get external reviewers for his proposed research projects because of the misinformation spread about Dr. Bridle.

51. Reputation impacts publication. It will be very difficult to find objective reviewers to peer review Dr. Bridle's publications. I have also noted over the past three years it has been very difficult publishing on topics in high-quality journals that do not conform with the non-questionable and non-critical narrative that the COVID-19 vaccines are "safe and effective" no matter what, even though concessions from public health officials, the scientific community, or data, tell a different story. Without high quality publications, this will also negatively impact professional credibility and funding opportunities.

52. The duty of a scientist in university is to question orthodoxy and Dr. Bridle's concerns have come to fruition, yet he has been punished for doing his job. This is a great injustice for a highly and uniquely qualified scientist in research and development of vaccines.

AFFIRMED BEFORE ME by Niel)
Karrow in the City of Guelph, in)

PERSONAL

Mailing Address: Department of Animal Biosciences
University of Guelph
Guelph, Ontario, Canada
N1G2W1
(519)-760-2468

Born: December 17, 1965

Marital Status: Married to Yan Hua Zhu
Daughters: Jordan and Sarah

EDUCATION:

1989 B. Sc. Biology
Minors in Biomedical Science and Animal Biosciences, University of Guelph, ON Canada.

1995 M. Sc. Biology
Area of specialization: Aquatic Toxicology, Advisors: D.G. Dixon and C. Neville (Ontario Ministry of Environment and Energy), Thesis title; "Sensitivity of rainbow trout sacfry and swim-up stages to sublethal concentrations of 3,4-dicholoraniline, 1,2-dichlorobenzene, and 2,4,5-trichlorophenol." University of Waterloo, ON, Canada

1999 Ph. D. Biology
Area of specialization: Immunotoxicology, Advisors: D.G. Dixon and N.C. Bols, and H.J. Boermans (University of Guelph), Thesis title; "Chemical mixture immunotoxicity to rainbow trout". University of Waterloo, ON, Canada

OTHER EDUCATION:

-Vanto Group Workshop, 2019. Rewriting the future of your organization and life. October 17-19, Guelph.
-Visiting scientist on sabbatical leave, 2016. College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China
-Visiting scientist on sabbatical leave, 2015. Aquatic Ecosystem and Aquaculture Lab. Ocean College, Zhejiang University, E201, Agriculture-Life-Environment Building, Zijingand Campus, 866 Yuhangtand Road, Hangzhou 310058, P.R. China.
-Course Re-design, 2006. Teaching Support Services, University of Guelph, May 23-26.
-19th Annual Teaching and Learning Innovations Conference, 2006. Pedagogies that challenge, University of Guelph, May 16th.
-Introduction to SELDI-TOF-MS, 2005. Ciphergen Biosystems, Inc. Woburn, MA, August 16-19.

-In-gel Protein Digestion and Identification by Mass Spectrometry, 2005. Department of Molecular Genetics and Biology, University of Guelph.
-Ontario Cancer Institute Microarray Tutorial: August 28, 2001, Toronto.
-Graduate Courses: Ecotoxicological Risk Characterization, Immunobiology, Modelling Environmental Pathways, Advanced Topics in Environmental Toxicology, Statistics and Experimental Design, and Special Topics in Research.
-1999 Society of Toxicology: Continuing education courses; Detecting and Quantifying Apoptosis, and Chemical Hypersensitivity

EDUCATIONAL AWARDS:

1999	Young Investigator Grant supported by the National Institute of Arthritis and Musculoskeletal and Skin Diseases (Grant# 1R13 AR 45962-01)
1997-1994	University of Waterloo Graduate Scholarship (UWGS)
1983	Headmaster's Award, St. John's Kilmarnock School First in Division in Waterloo Wellington Science and Engineering Fair
1982	Headmaster's Award, St. John's Kilmarnock School History and Geography Scholarship Third in Category in Canada Wide Science and Engineering Fair

EMPLOYMENT EXPERIENCE:

2023-2025	Adjunct Professor, Graduate School of Agricultural Science, Tohoku University, Sendai, Japan.
2018-2023	Adjunct Professor, Department of Animal Nutrition and Feed Science, Sichuan Agricultural University, 211 Hulmin Rd., Wenjiang District, Chengdu, Sichuan, 611130, P.R. China.
2017-2018	Chair Professor, College of Animal Science and Technology, Yangzhou University, Yangzhou, China.
2017	Full Professor, Department of Animal Biosciences, University of Guelph, Ontario, Canada
2016	Visiting Scholar, College of Animal Science and Technology, Yangzhou University, Yangzhou, China.
2011-17	Adjunct faculty appointment with Departments of Biomedical Science and Animal Biosciences, University of Guelph, Ontario, Canada
2008	Associate Professor, Department of Animal Biosciences, University of Guelph, Ontario, Canada
2002-2007	Assistant Professor, Department of Animal Biosciences, University of Guelph, Ontario, Canada

2007 Granted tenure 2007

Graduate Students/PDFs:

-Shadi Mamaghani (M.Sc. by coursework) Animal Biosciences, supervisor, 2004 (Program Manager, National Science Foundation, U of Toronto, Toronto)
-Leah Kabaroff (M.Sc. Toxicology) Animal Biosciences, supervisor, 2005 (Safety Specialist at Mount Sinai Hospital, Toronto, Ontario)
-Qiumei You (M.Sc.) Animal Biosciences, supervisor, 2006 (University of Guelph Animal Health Laboratory technician, Guelph, Ontario)
-Karen Phillips (M.Sc. Toxicology by coursework) Food Sciences, co-supervisor, 2006 (Senior Scientist, Intrinsik Environmental Science Inc., Calgary, Alberta)
-Jeremy Mount (M.Sc. Toxicology) Animal Biosciences, supervisor, 2007 (Veterinarian)
-Ivan Leyva (Ph.D.) Animal Biosciences, supervisor, 2007 (Product Manager at Thermo Fisher Scientific, Austin, Texas)
-James Godsmark (M. Sc. by coursework) Animal Biosciences, supervisor, 2008
-Rebecca Fisher (M.Sc. Toxicology) Animal Biosciences, co-supervisor, 2008
-Dr. Honghe Cao (post-doctoral fellowship) Animal Biosciences, co-supervisor, 2008 (University of Guelph Laboratory Services Division, Guelph, Ontario)
-Alicia Skelding (M.Sc. by coursework) Animal Biosciences, supervisor, 2009 (Veterinary Specialist in Anesthesia and Analgesia at Toronto Animal Health Partners Emergency and Specialty Hospital, Toronto)
-Yunee Kim (M.Sc. Toxicology) Animal Biosciences, supervisor, 2009 (Regulatory Affairs Associate at Gilead Sciences, U of Toronto, Toronto)
-Jennifer Ravin (M.Sc. course work) Animal Biosciences, supervisor, 2009
-Melissa Marshman (M.Sc. course work) Animal Biosciences, co-supervisor, 2009 (Veterinarian)
-Mainul Husain (Ph.D.) Animal Biosciences, co-supervisor, 2010 (Air Quality and Health Specialist, Regulatory Operations and Enforcement Branch at Health Canada).
-Eric Sauerteig (M.Sc. course work) Animal Biosciences, supervisor, 2010 (Manager, Project Office- Office of Campus Infrastructure and Sustainability, OntarioTech University-U of Waterloo)
-Chris Verschoor (Ph.D.) Animal Biosciences, supervisor, 2010 (Program Lead in Healthy Aging at Health Sciences North Research Institute)
-Sameer Pant (Ph.D.) Animal Biosciences, supervisor, 2010 (Assistant Professor Charles Sturt University, Wagga Wagga, New South Wales, Australia)
-Judy Stryker (M.Sc.) Animal Biosciences, supervisor, 2010
-Laura (Cain) Toms (M.Sc.) Animal Biosciences, supervisor, 2011 (Territory manager at Nestle Purina North America)
-Nancy Stonos (M.Sc. course work) Animal Biosciences, supervisor, 2012 (Technical and Regulatory Analyst at Animal Nutrition Association of Canada)
-Dr. Bhawani S. Sharma (post-doctoral fellowship/ research associate) Animal Biosciences, supervisor 2008-2012 (recovering from cancer)

-Philip Mead (M.Sc. Toxicology) Animal Biosciences, supervisor, 2013 (Chief Resident of Internal Medicine at OSF HealthCare)
-Rebecca Fisher (Ph.D. Toxicology) Animal Biosciences, supervisor, 2013
-Nitish Boodhoo (M.Sc. course work) Animal Biosciences, supervisor, 2013 (PDF, Pathobiology, U of Guelph, Ontario)
-Sanjay Mallikarjunappa (M.Sc. Toxicology) Animal Biosciences, supervisor 2013 (Ph.D. student University of Guelph, Guelph, Ontario)
-Dr. Rebecca Fisher-Heffernan (post-doctoral fellowship) Animal Biosciences, supervisor 2014-2015 (Research and Strategic Initiatives Facilitator, Lakehead University, Orillia)
-Heng Kang (M.Sc. coursework) Animal Biosciences, supervisor 2015 (Ph.D. student, Guelph)
-Steven Oh (Ph.D. Toxicology) Animal Biosciences, supervisor 2015
-Ziwei Li (M.Sc. Toxicology) Animal Biosciences, supervisor, 2015
-Qiumei You (Technician) Animal Biosciences 2006-15 (University of Guelph Animal Health Laboratory technician, Guelph, Ontario)
-Sarah Buttle (M.Sc. coursework Toxicology) Animal Biosciences, co-supervisor, 2017 (Veterinary Pharmaceutical Rep at NovaVive Inc.)
-Yunyun Guo (M.Sc. coursework Toxicology) Animal Biosciences, co-supervisor, 2017
-Lan You (M.Sc. Toxicology) Animal Biosciences, co-supervisor 2017 (GTA Regional manager at Robotique Zone 01 Robotics)
-Dr. Heba Attala (Research Associate) Animal Biosciences, co-supervisor 2017 (Research Associate, Pathobiology, U of Guelph, Ontario)
-Steven Oh (post-doctoral fellowship) Animal Biosciences, supervisor 2017 (Research Professor at Ewha Womans University, South Korea)
-Ziwei Li (Technician) Animal Biosciences 2015-2019 (University of Guelph Animal Health Laboratory technician, Guelph, Ontario)
-Alison Lee (Ph.D. Toxicology) Animal Biosciences, supervisor 2019 (Swine Researcher at Conestoga Meats)
-Samantha Dixon (M.Sc.) Animal Biosciences, co-supervisor 2019 (Buck Animal Hospital)
-Philip Mak (M.Sc. coursework Toxicology) Animal Biosciences, supervisor 2019 (Ph.D. student, Guelph)
-Sanjay Mallikarjunappa (Ph.D.) Animal Biosciences, supervisor 2019
-Emma Borkowski (Ph.D.) Pathobiology, co-supervisor 2019, (Assistant Professor, University of Surrey, Guildford, Surrey UK)
-Daniel Rothschild (M.Sc.) Animal Biosciences, co-supervisor 2019
-Danielle Naylor (M.Sc.) Animal Biosciences, supervisor 2020
-Nicole Moran (M.Sc. Toxicology) Animal Biosciences, supervisor 2021
-Ankita Sharma (Post-doctoral fellowship) Animal Biosciences, supervisor 2018-2021
-Misha McCaughan (M.Sc. coursework Toxicology) Animal Biosciences, supervisor 2021
-Ran Xu (Ph.D.) Animal Biosciences, supervisor 2023
-Kristen Lamers (Technician) Animal Biosciences 2019-2022
-Umesh Kumar Shandilya (Research Associate) Animal Biosciences, supervisor 2018-2022
-Caitlin McAllister (M.Sc. coursework) Animal Biosciences 2022
-Michael Ling (M.Sc. coursework) Animal Biosciences 2022
-Xiang Wu (M.Sc. coursework) Animal Biosciences 2022
-Tianna Sullivan (M.Sc.) Animal Biosciences, supervisor 2023

-Runzi Wang (M.Sc.) Animal Biosciences, supervisor 2023
-Yuancheng Liu (M.Sc. coursework Toxicology) Animal Biosciences, supervisor 2023
-Nicole Moran (Ph.D.) Animal Biosciences, supervisor
-Kristen Lamers (Ph.D.) Animal Biosciences, supervisor
-Nancy Gao (M.Sc. Toxicology) Animal Biosciences, supervisor
-Nieve Komadan (M.Sc. Toxicology) Animal Biosciences, supervisor
-Samantha Randle (M.Sc. coursework) Animal Biosciences, supervisor
-Spencer Leuschner (M.Sc. coursework) Animal Biosciences, supervisor
-Rebecka Sadler (M.Sc. Toxicology) Animal Biosciences, supervisor
-Samantha Dixon (Technician) Animal Biosciences 2023-2024

Graduate Student Committees:

-Zhumei Kang (M.Sc.) Animal Biosciences, committee member, 2005
-Maxwell Leung (M.Sc. Toxicology) Animal Biosciences, committee member, 2007
-Wendy Pearson (Ph.D.) Biomedical Sciences, committee member, 2007
-Corrine Hamilton (Ph.D.) Pathobiology, committee member, 2008
-Spencer Russell (Ph.D.) Pathobiology, committee member, 2008
-Mohsen Jafarikia (Ph.D.) Animal Biosciences, committee member, 2008
-Gordon Mitchell (Ph.D.) Pathobiology, committee member, 2008
-George Girgis (Ph.D.) Animal Biosciences, committee member, 2009
-Katja Linher (M.Sc.) Animal Biosciences, committee member, 2009
-Girish Channarayapatnak (Ph.D.) Animal Biosciences, committee member, 2009
-Mamun Or-Rashid (Postdoctoral fellowship) Animal Biosciences, co-supervisor, 2009
-Paulina Wiercinska (M.Sc.) Animal Biosciences, committee member, 2009
-Shannon Cartwright (M.Sc.) Pathobiology, committee member, 2010
-Michael Steele (Ph.D.) Animal Biosciences, committee member, 2011
-Meghan Hewitt (M.Sc.) Animal Biosciences, committee member, 2011
-Anooshrokh Rakhshandeh (Ph.D.) Animal Biosciences, committee member, 2011
-John Doelman (Ph.D.) Animal Biosciences, committee member, 2012
-Jason Baley (M.Sc.) Animal Biosciences, committee member, 2012
-Brandon Walters (M.Sc. Toxicology) Animal Biosciences, committee member, 2012
-Melissa Mortson (M.Sc.) Animal Biosciences, committee member, 2012
-Kathleen Thompson (Ph.D.) Pathobiology, committee member, 2012
-Louis Dionissopoulos, (Ph.D.) Animal Biosciences, committee member 2013
-Liu Hong Chen (Ph.D.) Animal Biosciences, co-supervisor 2013
-Lyle Shepherd (M.Sc.) Animal Biosciences, committee member 2013
-Lesley Berghuis (M.Sc.) Pathobiology, committee member 2013
-Mauren Crump (M.Sc.) Animal Biosciences, committee member 2015
-Bing Liu (M.Sc.) Animal Biosciences, committee member 2016
-Marlene Paibomesai (Ph.D.) Pathobiology, committee member 2016
-Shanmugasundaram Karuppuswamy (Ph.D.) Biomedical Science, committee member 2016
-Jamie Hooft (Ph.D.) Animal Biosciences, committee member 2017
-Monica Baquero (Ph.D.) Pathobiology, committee member 2017
-Luis Pena Ortega (Ph.D.) Animal Biosciences, committee member 2016

-Bo Pan (Ph.D.) Animal Biosciences, committee member 2018
-Hailey Hunter (M.Sc.) Integrative Biology, committee member 2018
-Kevin Stinson (Ph.D.) Pathobiology, committee member 2018
-Rebecca Egan (D.V.Sc.) Pathobiology, committee member 2019
-Kristen Lamers (M.Sc.) Clinical Studies, committee member 2019
-Mariana Roedel (M.Sc.) Animal Biosciences, committee member 2020
-Matthew Wong (M.Sc.) Animal Biosciences, committee member 2020
-Reza Akbari Moghaddam Kakhki, (Ph.D.) Animal Biosciences, committee member 2020
-Nasrin Setayesh (M.Sc.) Pathobiology, committee member 2020
-Michelina Crosbie (M.Sc.) Animal Biosciences, committee member 2020
-Lauren Hansen (M.Sc.) Animal Biosciences, committee member 2020
Mohaammed Boareki (Ph.D.) Animal Biosciences, committee member 2021
-George Hall (Ph.D.) Animal Biosciences, committee member 2021
-Chenchen Tang (M.Sc.) Animal Biosciences, committee member 2021
-Sudhanshu Sudan (Ph.D.) Animal Biosciences, committee member 2022
-Shannon Cartwright (Ph.D.) Pathobiology, committee member, 2022
-Emily Kim (Ph.D.) Animal Biosciences, committee member 2023
-Jiali Chen (Ph.D.) Animal Biosciences, committee member 2023
-Aileen MacLellan (Ph.D.) Animal Biosciences, committee member 2023
-Olivia Willoughby (Ph.D.) Animal Biosciences, committee member
-Alexandra Mick (M.Sc.) Animal Biosciences, committee member
-Kathryn Burns (M.Sc.) Animal Biosciences, committee member
-Amanda Mansz (D.V.Sc.) Pathobiology, committee member
-Kristin Wythe (M.Sc.) Pathobiology, committee member
-Raelyn McCurdy (M.Sc.) Animal Biosciences, committee member
-Tess Altvater-Hughes (Ph.D.) Pathobiology, committee member
-Julie Kim (Ph.D.) Population Medicine, committee member
-Wenyi Fan (Ph.D.) Animal Biosciences, committee member
-Lori Ogilvie (M.Sc.) Animal Biosciences, committee member
-Anna Garland (Ph.D.) Animal Biosciences, committee member
-Elise Lafleur Lariviere (M.Sc.) Animal Biosciences, committee member
-Linyi Tang (M.Sc.) Biological Engineering, committee member
-Carmon Co (D.V.Sc.) Pathobiology, committee member
-Linyi Tang (M.Sc.) School of Engineering, committee member
-Maddie Borland (M.Sc.) Animal Biosciences, committee member
-Tesa Kinasih (Ph.D.) Animal Biosciences, committee member

Visiting Scholars:

-Dr. Herman Boermans (Sabbatical) Biomedical Sciences, Univeristy of Guelph, 2009
-Dr. Yong Jun Li, (Sabbatical) College of Animal Science & Technology, Yangzhou University, Yangzhou, Jiangsu, China, 2011
-Laila Schnekel (M.Sc.), visiting graduate student, Universidade Federal Do Rio Grande Do Sul, Brazil, 2012
-Dr. Jialang Zhang (Sabbatical) West Campus, Animal Science Department, College of Animal Science, Yangtze University, Jingzhou, Hubei, China, 2013

-Yunyun Guo, visiting scholar, Hunlun Buir Center for Disease Control and Prevention, Hulun Buir City, Inner Mongolia, 2015
-Dr. Binglei Shen, visiting scholar, College of Animal Science and Veterinary Medicine, Heilongjiang Bayi Agricultural University, Daqing, 2015
-Dr. Yongjiang Mao, (Sabbatical) College of Animal Science & Technology, Yangzhou University, Yangzhou, Jiangsu, China, 2015
-Dr. Chunfang Wang, visiting scholar, College of Fisheries, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China 2018-21
-Cheng Ke (M.Sc.), visiting graduate student, College of Fisheries, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China 2019
-Dr. Umesh Kumar Shandilya, visiting scholar, Animal Biotechnology Division, National Bureau of Animal genetic Resources, Haryana, India 2019
-Jiahe Guo (M.Sc.), College of Animal Science & Technology, Yangzhou University, Yangzhou, Jiangsu, China, 2019
-Krishani Wijeshinghe (MSc.) Institute of Agriculture, University of Peradeniya, Sri Lanka
-Yan Liang (Ph.D.), College of Animal Science & Technology, Yangzhou University, Yangzhou, Jiangsu, China, 2023
-Yang Lui visiting scholar, Coldwater Fish Research Laboratory, Department of Aquaculture, Heilongjiang River Fisheries Research Institute, Chinese Academy of Fishery Sciences, Harbin.

Undergraduate Student Supervision:

-Elizabeth Courtney (Summer Student) Ontario Veterinary College, 2004 (Veterinarian)
-Jeremy Mount (Summer Student) Human Biology, 2004 (Veterinarian)
-Sergio Aguirre (Summer Student) Animal Biosciences, 2005 (Co-founder and CEO of Epineuron – Richard Ivey School of Business, Toronto)
-Yunee Kim (Summer Student) Animal Biosciences, 2005
-Robyn Slavinski (Summer Student) Animal Biosciences, 2005 (Veterinarian)
-Jessica Hartley (Hons. Thesis Project Student) Molecular Biology and Genetics, 2005 (Program Director for the MSc in Genetic Counselling at U of Manitoba, Manitoba)
-Carl McNicoll (Summer Student) Ontario Veterinary College, 2002-2005 (Veterinarian CFIA)
-Christian Sandrock (Hons. Thesis Project Student) Biomedical Sciences, 2006 (Laboratory Technician at University of Guelph Animal Health Laboratory)
-Julie Martin (Summer Student) Biomedical Sciences, 2006
-Tyler O'Neill (Summer Student) Animal Biosciences, 2006 (Veterinarian)
-Graham Biggar (Summer Student) Animal Biosciences, 2007-2008 (Veterinarian)
-Elise Shine (Hons. Thesis Project Student) Animal Biosciences, 2007
-Laura Cain (Hons. Thesis Project Student) Animal Biosciences, 2007
-Eric Sauerteig (Hons. Thesis Project Student) Animal Biosciences, 2009
-Sarah Taylor (Hons. Thesis Project Student) Animal Biosciences, 2009 (Veterinarian)
-Cara Yu (Summer Student) Biomedical Sciences, 2009 (Veterinarian)
-Trevor Giesler (Hons. Thesis Project Student) Animal Biosciences, 2010
-Rachael Nehir Oktem (Summer student) Animal Biosciences, 2010

-Caroline Balch (Hons. Thesis Project Student) Animal Biosciences, 2011 (Medical Laboratory Technologist in Kingston General Hospital clinical genetics lab, Kingston)
-Megan Whaley (Hons. Thesis Project Student) Animal Biosciences, 2011 (M.Sc. student at University of Guelph, Guelph)
-Samantha Medeiros (Hons. Thesis Project Student) Animal Biosciences, 2012 (Floridale Feed Mills, Floridale)
-Rachel Cliff (Hons. Thesis Project Student) Animal Biosciences, 2012 (M.Sc. student at University of British Columbia)
-Katherine Goliboski (Hons. Thesis Project Student) Animal Biosciences, 2012 (Veterinary Assistant, Brantford)
-Mikayla Ross (Hons. Thesis Project Student) Animal Biosciences, 2012 (Semex Alliance Inc.)
-Samantha Balthes (Hons. Thesis Project Student) Animal Biosciences, 2013
-Chris Hylands (Hons. Thesis Project Student) Biomedical Science, 2013 (QA Inspector, Novartis, Mississauga)
-Andrew Brereton (Hons. Thesis Project Student) Molecular Biology and Genetics, 2013 (M.Sc. student at Oregon State University, Oregon)
-Jillian Wegelin (Hons. Thesis Project Student) Animal Biosciences, 2013 (Veterinary technician)
-Mitra Jafari (Hons. Thesis Project Student) Animal Biosciences, 2013
-Vikram Bettadapura (Hons. Thesis Project Student) Animal Biosciences, 2013
-Katherina Welsh (Hons. Thesis Project Student) Nutrition, 2013 (Clinical nutritionist)
-Irene Lui (Summer student) Animal Biosciences, 2013 (Veterinarian)
-Alison Lee (Hons. Thesis Project Student) Animal Biosciences, 2014
-Julie Nadeau (Hons. Thesis Project Student) Animal Biosciences, 2014 (Veterinarian)
-Gabrielle Ene (Hons. Thesis Project Student) Animal Biosciences, 2014-2015
-Jasmine Carter (Hons. Thesis Project Student) Biomedical Science, 2014-2015
-Alisha Wornath-Vanhumbeck (Hons. Thesis Project Student) Animal Biosciences, 2014-2015
-Leighanna Yip (Hons. Thesis Project Student) Animal Biosciences, 2015
-Erin Syjueco (Summer student) Animal Biosciences, 2015 (Veterinarian)
-Kevin Barbosa (Summer student) Animal Biosciences, 2015
-Sean Roberts (Hons. Thesis Project Student) Animal Biosciences, 2016
-Philip Mak (Hons. Thesis Project Student) Animal Biosciences, 2016
-Kristen Lamers (Hons. Thesis Project Student) Animal Biosciences, 2016
-Michael Alcorn (Summer student) Animal Biosciences, 2016
-Alexandra Code (Hons. Thesis Project Student) Animal Biosciences, 2017-2018
-Oren Furmanov (Hons. Thesis Project Student) Animal Biosciences, 2017-2018
-Nicole Moran (Hons. Thesis Project Student) Animal Biosciences, 2018
-Theepan Tharumalingam (Summer student) Animal Biosciences, 2018-2019
-Tianna Sullivan (Hons. Thesis Project Student) Animal Biosciences 2018-2019
-Aisha Fong (Hons. Thesis Project Student) Animal Biosciences 2018
-Joey Ma (Hons. Thesis Project Student) Animal Biosciences 2018-2019
-Yieshna Bhujoo (Hons. Thesis Project Student) Biomedical Science 2019
-Tianna Sullivan (Summer student) Animal Biosciences 2019

-Yashi Zheng (Summer student, Hons. Thesis Project Student) Animal Biosciences 2019-2020
-Elizabeth Teel (Summer student) Animal Biosciences 2019
-Runzi Wang (Hons. Thesis Project Student) Animal Biosciences 2019-2020
-Victoria De Carvalho (Hons. Thesis Project Student) Animal Biosciences 2019-2020
-Ashley-Gail Lyons (Hons. Thesis Project Student) Animal Biosciences 2019-2020
-Gee-Zou J Wang (Hons. Thesis Project Student) Animal Biosciences 2020
-Giselle Kalnins (Hons. Thesis Project Student) Biomedical Sciences 2020
-Caitlin McAllister (Hons. Thesis Project Student) Animal Biosciences 2020
-Nancy Gao (Summer student & Hons. Thesis Project Student) Animal Biosciences 2021-2022
-Megan Woo (Hons. Thesis Project Student) Animal Biosciences 2021-2022
-Claudia Mercurio (Hons. Thesis Project Student) Biomedical Sciences 2022
-Sophie Tieu (Summer student) Animal Biosciences 2022
-Teeba Ismail (Hons. Thesis Project Student) Animal Biosciences 2022-2023
-Rebecka Sadler (Summer student) Animal Biosciences 2023
-Guyue Renke (Hons. Thesis Project Student) Animal Biosciences 2023-2024

High School Student Supervision:

-Alice Meng Gao, Guelph Collegiate Vocational Institute, Guelph, Ontario, 2009
-Stanley Lien, St. John's Kilmarnock, Breslau, Ontario, 2009
-Research project co-advisor with Dr. Louise Temple (James Madison Univerisity, Virginia) for students Joseph Burns and Benjamin Ghaemmaghami, Eastern Mennonite High School, Harrisonburg, Virginia, 2013

Course Lecturing:

-Graduate Course in Comparative Immunology, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China 2022 (32 hours) 2022
-Graduate Course in Nutritional Immunology, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China 2020 (30 hours)
-Graduate Course in Animal Health, College of Animal Science and Technology, Yangzhou University, Yangzhou, China 2019 (20 hours)
-Graduate Course in Animal Health, Department of Animal Nutrition and Feed Science, Sichuan Agricultural University, Chengdu, China 2018 (20 hours)
-Graduate Course in Animal Health, College of Animal Science and Technology, Yangzhou University, Yangzhou, China 2018 (20 hours)
-Graduate Course in Comparative Immunology, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, 430070, P.R. China 2016-19 (32 hours)
-Graduate Course in Comparative Immunology, College of Animal Science and Technology, Yangzhou University, Yangzhou, China 2017 (20 hours)
-ANSC3270 Animal Disorders 2017-22 (60 hours)
-ANSC4650 Comparative Immunology 2006-22 (70 hours)

-ANSC 4080 Environmental Management and Animal Health 2004-5 (1 hour)
-AGR2350 Animal Production Systems and Industry 2004-6 (50 hours)
-AGR1250 Food System Trends and Issues 2003 (15 hours)
-ANSC4490 Applied Endocrinology 2003-10 (3 hour)
-TOX6200 Advanced Topics in Toxicology 2003-10 (1 hour)
-TOX4000 Medical Toxicology 2003-12 (3 hours)
-ANSC6330 Genomics and Proteomics for Animal Sciences 2004-6 (36 hours)
-ANSC4090 Applied Animal Behaviour 2005-10 (1 hour)
-ANSC4350 Experiments in Animal Biology 2009-12 (15 hour)
-POPM4230 Animal Health 2013 (70 hours)

Graduate Student Exam Committee Service:

-John Peacock (M.Sc.), Animal Biosciences, 2001
-Jennifer Beveridge (M.Sc.), Pathobiology, 2001
-H.V.L.N. Swamy (Ph.D.), Animal Biosciences, 2001
-Mamiko Shimizu (M.Sc.), Animal Biosciences, 2002
-Jennifer Stewart (M.Sc.), Animal Biosciences, 2002
-Paul Dyce (M.Sc.), Animal Biosciences, 2003
-Shankar Chowdhury (Ph.D.), External Examiner Representative, Animal Biosciences, 2003
- Muthafar Al-Haddawi (D.V.Sc.), Pathobiology, 2006
-Sergey Duvanov (M.Sc.) Animal Biosciences, 2008
-Gordon Mitchell (Ph.D.), Pathobiology, 2008
-Katja Linher (Ph.D.), Animal Biosciences, 2009
-Paulina Wiercinska (M.Sc.) Animal Biosciences, 2009
-Sabrina Greenwood (Ph.D.) Animal Biosciences, 2009
-Sarah Scapinello, (M.Sc.) Pathobiology, 2009
-Ontario Graduate Scholarship Evaluation Committee, 2010
-Kathleen Thompson (Ph.D.) Pathobiology, 2010
-Fariba Izadi Shavakand (Ph.D.) External Examiner, Animal Science, University of British Columbia, 2010
-Jamie Hooft (M.Sc.) Animal Biosciences, 2010
-Meghan Hewitt (M.Sc.) Animal Biosciences, 2011
-Anooshrokh Rakhshandeh (Ph.D.), Animal Biosciences, 2011
-Jason Baley (M.Sc.), Animal Biosciences, 2012
-Joel David (M.Sc.) External Examiner, Department of Medical Science, University of Calgary, July 17, 2013
-Caroline Gonano (M.Sc.) Examining Chair, Animal Biosciences, 2013
-Matthew Gray (Ph.D.) Examining Chair, Animal Biosciences, 2013
-Lesley Berghuis (M.Sc.) Exam Committee, Pathobiology, Committee member 2013
-Janelle Kelly (M.Sc.) Examining Chair, Animal Biosciences 2014
-Morgan Overvest (M.Sc.) Examining Chair, Animal Biosciences 2015
-Bing Liu (M.Sc.) Animal Biosciences, 2016
-Marko Rudar (Ph.D.), Animal Biosciences, 2016
-Victoria Asselstine (M.Sc.), Animal Biosciences, 2018
-Kristen Wight (M.Sc.), Animal Biosciences, 2018

-Kevin Stinson (Ph.D.) Pathobiology, 2018
-Rebecca Egan (D.V.Sc.) Pathobiology, 2019
-Kristen Lamers (M.Sc.) Clinical Studies 2019
-Seyedmehdi Emam (PhD) Pathobiology, 2019
-Nasrin Setayesh (M.Sc.) Pathobiology, 2020
-Yiru Sheng (M.Sc.) Integrative Biology, 2020
-Shannon Cartwright (Ph.D.) Pathobiology 2022
-Shannon Beard (Ph.D.) Pathobiology, 2023
-Aileen MacLellan (Ph.D.) Animal Biosciences, 2023

Graduate Student Qualifying Exam Committee Service:

-Wendy Pearson (Ph.D.), Biomedical Science, 2005
-Gordon Mitchell (Ph.D.), Pathobiology, 2005
-Anooshrokh Rakhshandeh (Ph.D.), Animal Biosciences 2006
-George Girgis (Ph.D.), Animal Biosciences, 2006
- Milton Daley (Ph.D.), Animal Biosciences, 2007
-Girish Channarayapanak (Ph.D.), Animal Biosciences, 2007
-John Doelman (Ph.D.), Animal Biosciences, 2008
-Melkaye Melka (Ph.D.), Animal Biosciences, 2008
-Chandrika Senthilkumaran's (Ph.D.), Pathobiology, 2011
-Krishna Yekkala (D.V. SC.), Pathobiology, 2011
-Jamie Hooft (Ph.D), Animal Biosciences, 2011
-Marlene Paibomesai (Ph.D.), Pathobiology, 2012
-Louis Dionissopoulos, (Ph.D.), Animal Biosciences, 2012
-Lauri Wagter Lesperance (Ph.D.), Pathobiology, 2012
-Shanmugasundaram Karuppuswamy (Ph.D.), Biomedical Science, 2012
-Amanda Mansz (D.V.Sc.), Pathobiology, 2013
-Shirene Singh (Ph.D.), Pathobiology, 2013
-Marko Rudar (Ph.D.), Animal Biosciences, 2013
-Monica Baquero (Ph.D.), Pathobiology, 2014
-Emily Miller (Ph.D.), Animal Biosciences, 2014
-Teresa Casey (Ph.D.), Animal Biosciences, 2014
-Wilfredo Mansilla (Ph.D.) Examining Chair, Animal Biosciences, 2014
-Alison Flemming (Ph.D.), Animal Biosciences, 2015
-Walter Sanchez-Suarez (Ph.D.), Examining Chair, Animal Biosciences, 2015
-Christopher Powel (Ph. D.), Examining Chair, Animal Biosciences, 2016
-Laura Bassel (Ph.D.), Examining Committee, Pathobiology, 2016
-Seyedmehdi Emam (Ph.D.), Pathobiology, 2016
-Flavia Damasceno (Ph.D.), Examining Chair, Animal Biosciences, 2016
-Emma Borkowski (Ph.D.), Examining Committee, Pathobiology, 2017
-Mariana Roedell (Ph.D.), Examining Committee, Animal Biosciences, 2018
-Stephanie Lam (Ph.D.), Examining Committee, Animal Biosciences, 2018
-Reza Akbari Moghaddam Kakhki (Ph.D.), Animal Biosciences, 2018
-Xindi Yin (Ph.D.), Examining Chair, Animal Biosciences, 2019
-Michelle Lavery (Ph.D.), Examining Chair, Animal Biosciences, 2019

-Alison Lee (Ph.D.), Examining Committee, Animal Biosciences, 2019
-Emma Borkowski (Ph.D.), Examining Committee, Pathobiology, 2019
-Victoria Asselstine (Ph.D.), Examining Committee, Pathobiology, 2019
-Sudhanshu Sudan (Ph.D.), Examining Committee, Animal Biosciences, 2020
-Shannon Beard (Ph.D.), Examining Committee, Pathobiology, 2020
-Ran Xu (Ph.D.), Examining Committee, Animal Biosciences, 2020
-Jia Li Chen (Ph.D.), Examining Committee, Animal Biosciences, 2020
-Emily Kim (Ph.D.), Examining Committee, Animal Biosciences, 2020
-Aileen MacLellan (Ph.D.), Examining Committee, Integrative Biology, 2020
-Anna Garland (Ph.D.), Examining Committee, Animal Biosciences, 2021
-Xiaoshu Zhan (Ph.D.), Examining Chair, Animal Biosciences, 2021
-Nooshin Nikmararam (Ph.D.), Examining Committee, School of Engineering, 2021
-Nicole Moran (Ph.D.), Examining Committee, Animal Biosciences, 2023

Administrative Service:

-Office of Research contact for the Department of Animal Biosciences, 2002-4
-Ontario Agriculture College Communications Committee, 2002-4
-Co-chaired the Disease Resistance Symposium at the 7th World Congress on Genetics Applied to Livestock Production, Montpellier, France, Aug. 19-23, 2002
-Council member for the University of Guelph Faculty Association, 2003-2005
-Member of the University of Guelph Salary Negations Committee, 2003-2005
-Member of the Department of Animal Biosciences Undergraduate Teaching Committee, 2004-2012
-Judged Molecular Biology and Genetics undergraduate thesis project student's posters, 2005
-OAC representative of the University of Guelph Mass Spectrometry Committee, 2005-2010
-Undergraduate Ontario Universities Fair, September 28-30, 2007
-Member of OAC delegation to Northwestern A&F University, April 13-17, 2009, Yangling, Shaanxi, China
-Chaired Animal Proteins (Section 5.3) at the 5th Anniversary of Protein and Peptide Conference (PepCon-2012) March 23-25, 2012, Beijing, China
-Departmental Graduate Teaching Committee member, 2012-present
-Departmental Research Committee, 2012-present
-Promotion and Tenure Committee, 2012-2016
-Mycotoxin detection and risk assessment panel member at the Alltech Symposium, Lexington Kentucky, May 19-21, 2013
-Chaired Veterinary Medicine and Treatment, Animal Models and Testing, and Animal Ecology (Sections 6, 7, and 8) at the 1st International OMICS Group Conference on Animal & Dairy Sciences, July 23-24, 2013, Las Vegas, Nevada
-Participated in the Research Strategy Workshop for Stakeholders in the Ontario Goat Sector, Guelph, On. Oct. 3, 2013
-Participated in the Ontario Veal Research Strategy Development Meeting, Guelph, On. Oct. 2, 2013
-Planning committee for ASAS-ADSA-CSAS Joint Annual Meeting section titled "Small

Ruminant: Sustainable Small Ruminant Production Strategies to Meet Global Demands" July 23, 2014, Kansas City, MO
-Client reviewer of the services and functions of U of G Animal Care Services 2014
-Judge at the Waterloo Wellington Science and Engineering Fair, Waterloo, April 8, 2014
-Hosted visiting scientist Dr. Kieran Meade & Bioscience Research Department, Animal & Grassland Research and Innovation Centre, Teagasc, Grange, Co. Meath, Ireland, April 25-26, 2014
-Animal Biosciences Poultry Nutrition Faculty Search Committee, 2014
-Chaired CSAS Graduate Student Oral Presentation Competition at the ADSA-ASAS-CSAS Joint Annual Meeting, 2014, Kansas City, Missouri, July 20-24
-Immunotoxicology consultant for the Safety Evaluation Centre of Shenyang Research Institute of Chemical Industry (SYRICI), 2014, Shanyang, China, August 2-5
-Animal Biosciences representative hosted dairy science delegation from Guyana September 18, 2014
-Animal Biosciences Beef Nutrition Faculty Search Committee 2015
-Animal Biosciences Graduate Student Committee, 2016-2021
-University of Guelph Genomics Facility User Committee, 2014-2018
-Faculty member of the University of Guelph's undergraduate and graduate program in Toxicology, 2004-present.
-Faculty member of the University of Guelph's graduate program in Bioinformatics, 2011-Present
-Animal Biosciences Animal Physiology Faculty Search Committee 2017-18
-Editorial board of Revista de la Facultad de Medicina Veterinariay de Zootecnia, which publishes case reports as well as original articles, reviews, and opinion articles in all areas of veterinary medicine and animal science 2018
-External Ph.D. defence examiner for graduate students (Q. Zhao, S.H. Qamar, B. He, E. Kuang Yi Wen) at Sichuan Agricultural University, Chengdu, Sichuan, P.R. China, 2018
-Animal Biosciences Graduate Student Coordinator, 2019-2020
-Animal Biosciences Aquaculture Faculty Search Committee, 2019
-Animal Biosciences Acting Department Chair 2019-2020
-Animal Biosciences Graduate Program Assistant Search Committee, 2020
-Faculty member of the University of Guelph's graduate program in One Health, 2020-Present
-Promotion and Tenure Committee, 2020-Present
-Guest editor for special Toxins issue on Remediation Strategies for Mycotoxin in Animal Feed of Toxins 2021
-Canadian COVID Care Alliance (CCCA) Science and Medical Advisory Committee 2021-2022
-Chief Scientific Officer of ImmunoCeutica Inc., Cambridge, ON, PO Box 27069 Clair Rd. Guelph, ON N1L0A6, 2022

2002-2000 Postdoctoral Fellowship with Dr. B. Mallard, Department of Pathobiology, University of Guelph, Guelph, Ontario, Canada
Supervised two graduate students research projects and initiated the development of a bovine endocrine-immune microarray chip.

2000 Fall Sessional Lectures
Undergraduate Biomedical Toxicology 4000. Sessions included respiratory, renal, hepatic, dermal toxicology and immunotoxicology.

2000-1999 Research Associate with Dr. K.L. White, Jr., Department of Pharmacology and Toxicology, Medical College of Virginia- Virginia Commonwealth University, Richmond, VA, USA
Principal Investigator for contact hypersensitivity studies, and Study Director for several immunotoxicity studies conducted for the National Institute of Health Sciences (NIEHS).

Course Lecturing:
Supervised two graduate students' rotational projects. I was also involved in lecturing graduate courses in immunotoxicology, chemical hypersensitivity and endocrinology.

PHTX/ENVS 691 Environmental Toxicology: Endocrine disruptors in immunotoxicology
PMC536 Principles of Pharmacology and Toxicology: Dermal toxicology
PMC 535 Introduction to Toxicology: Endocrine toxicology, Immunotoxicology

1999 Immunotox Inc., Richmond, VA, USA
Contracted to develop a holistic cell-mediated immune model for evaluating antisense oligonucleotide anti-inflammatory properties in mice.

1998 Post Doctorate Fellowship with Dr. K.L. White, Jr., Department of Pharmacology and Toxicology, Medical College of Virginia- Virginia Commonwealth University, Richmond, VA, USA
Supervised a graduate student rotational project titled, "Evaluating lymphocyte subsets and cytokine mRNA expression in draining lymph nodes following cinnamaldehyde exposure." A travel grant to the Experimental Contact Dermatitis Research Group was awarded to us for this research.
1998-1997 Consulting Scientist for Environment Canada, Burlington, ON, Canada
Evaluated the immunotoxicity of PAH contaminated sediments and sewage treatment plant effluents in the Hamilton Harbour using caged rainbow trout.

1996-1995 Study Director, University of Guelph, Guelph, ON, Canada
Directed several sublethal creosote microcosm exposure studies. This involved planning, training personnel, and supervising two microcosm field studies to evaluate creosote sublethal toxicity to rainbow trout. Biomarkers of exposure included immune parameters, growth, EROD activity, endocrine response, bile metabolites and DNA adduct formation.

1998-1991 Teaching Assistant, Department of Biology, University of Waterloo, Waterloo, ON, Canada
Demonstrated in numerous undergraduate laboratories including, animal physiology, genetics, toxicology, and immunology. Co-supervised three undergraduate special project students.

1993-1991 Laboratory Technician, BAR Environmental Inc. Guelph, ON, Canada

Technical duties: sediment toxicity testing; benthos taxonomy; spottail shiner collection along Lake Superior; toxicity testing using rainbow trout, Chinook salmon, fathead minnows, *D. magna*, *C. dubia*, *D. pulex*, Lemna, and Rotifers; and Trent River environmental impact assessment.

1990 Fisheries Biologist, Environmental Advisory Services, Guelph, ON, Canada
1990 Great Lakes Fish Collection of Young of the Year Spottail Shiners for the Ministry of the Environment, and brook trout habitat assessment for the Uxbridge and Beaverton Rivers.

1989-1990 Research Assistant, Integrated Explorations Environmental Consultants, Guelph, ON, Canada
Train laboratory personnel to conduct *D. magna* and rainbow trout bioassays and data entry for MISA program.

Technical duties: Saltwater bioassays using mysid shrimp and sheepshead minnows; brook trout stomach content taxonomy; taxonomic identification of benthos from Bass Lake, Misema River, Sir Adam Beck Reservoir and St. Lawrence River (Cornwall) projects; establish quality assurance/quality control monitoring program for laboratory invertebrate, vertebrate and microphyte stocks; analytical and microbiological water quality analysis.

Field work: 1989 Lake Simcoe Whitefish Spawning Shoal Survey; Kincardine sewage treatment plant outflow repair; installation of a destratifier on Guelph Lake; Lakeview water intake inspection; 1991 St. Lawrence benthological Survey in Cornwall; and 1991 Lake Simcoe whitefish and lake trout spawning shoal survey.

1989 Contracted Fisheries Biologist, Ministry of Natural Resources, Owen Sound, ON, Canada
Access point creel survey along Lake Huron.
1988-1989 Research Assistant for Dr. P. Conlon, Department of Biomedical Sciences, University of Guelph, Guelph, ON
Conducted experiments to evaluate the effectiveness of the immunomodulating drug, levamisole, in treating dairy calves infected with IBR virus. Mechanisms of action were explored, using chemiluminescence to assess alveolar macrophage activity, and various therapeutic drugs to modulate respiratory burst.

1987 Research Assistant, Cambridge Horticulture Research Station, University of Guelph, Guelph, ON, Canada
Involved in crop and pesticide research.

1983-1986 **Camp Tawingo**- Counsellor
Cowdenknowles Farms- Swine and crop management
Stoltzlane Farms- Dairy and crop management
University of Waterloo- Usher in Humanities Theatre

Graduate Student Theses:

T. Sullivan (M.Sc.) 2023. Forming the basis for genetic selection of stress resilient dairy heifers: Characterization of the bovine stress response.

M. Wang (M.Sc.) 2023. An Investigation into the use of butyrate to reduce risk of endotoxemia during lethal bacterial lipopolysaccharide challenge in larval zebrafish.

R. Xu. (Ph.D.) 2023. In vitro toxicity assessment of mycotoxins using bovine mammary epithelial cells and their remediation using yeast-based adsorbents.

N. Moran (M.Sc.) 2021. An investigation into the potential use of 6-gingerol to combat endotoxemia and reduce inflammation during tissue trauma in larval zebrafish.

D. Naylor (M.Sc.) 2020. The ovine inflammatory response to lipopolysaccharide and association with the stress response phenotype.

S. Mallikarjunappa (Ph.D.) 2019. Johne's disease in dairy cattle: Validation of genetic markers and assessment of salivary gland transcriptome.

S. Dixon (M.Sc.) 2019. Identifying hepatic genes regulating the ovine response to gastrointestinal nematodes.

A. Lee (Ph.D.) 2019. Effect of microalgae or fish oil supplementation in late gestation sows on piglet health.

E. Borkowski (Ph.D.) 2019. Investigation of the immune response of sheep to gastrointestinal nematode infection under Ontario grazing conditions to identify genetically resistant animals.

L. You (M.Sc.) 2017. Effect of fish oil or algae meal supplementation on the fetal and neonatal endotoxin-induced stress response.

Z. Li (M.Sc.) 2015. In vitro assessment of Saccharomyces cerevisiae derivatives using bovine epithelial cells, macrophages, and Mycobacterium avium spp. paratuberculosis.

S. Oh (Ph.D.) 2014. Assessing immunomodulatory effect of Penicillium mycotoxins using a bovine macrophage cell line (BOMACs)

S. Mallikarjunappa (M.Sc.) 2013. Breed-specific cytokine expression in Holstein-Friesian and Jersey calves infected with Mycobacterium avium subsp. Paratuberculosis.

R. Fisher (Ph.D.) 2013. Maternal supplementation with fishmeal protects against late gestation endotoxin-induced fetal programming of the ovine hypothalamic-pituitary-adrenal axis.

P. Mead (M.Sc.) 2013. Infection of monocyte-derived macrophages with a reporter Mycobacterium avium spp. paratuberculosis (MAP) strain: validation of the susceptibility SNP (-298A>G) in the bovine MIF gene.

L. Cain (M.Sc.) 2011. Variation in the endotoxin-induced ovine cortisol response and its association with immune function.

J. Stryker (M.Sc.) 2010. Evaluation of dietary fish meal or soybean meal supplementation effects on ovine immune response during pregnancy and lactation

C. Verschoor (Ph.D.) 2010. Genetic variation in candidate inflammatory-related genes and its relation to infectious bovine disease.

S. Pant (Ph.D.) 2010. Identification of SNPs and chromosomal regions associated with inflammatory disease resistance in Holstein dairy cattle.

M. Hosain (Ph.D.) 2010. Using BALB/c mice as a model of food allergy to study gene expression profiles in response to common food allergens.

Y. Kim (M.Sc.) 2009. Evaluation of local and systemic bovine host defense protein profiles following intramammary challenge with various strains of *Staphylococcus aureus*.

A. Skelding (M.Sc.) 2009. Association of SNP in the IL-12 and IL-23 receptor genes with milk SCS and antibody response to MAP infection in dairy cattle.

R. Fisher (M.Sc.) 2008. Effect of maternal endotoxemia on the offspring hypothalamic-pituitary-adrenal axis and fever response later in life.

I. Leyva (Ph.D.) 2007. Association of SNPs in the CCL2, CXCL8, CCR2, and CXCR1 genes with health and production traits in Canadian Holsteins.

J. Mount (M.Sc.) 2007. Inflammation induced chemokine gene expression in bovine mammary gland explants.

Q. You (M.Sc.) 2006. Evaluation of immune responsiveness and hepatic gene expression in high, medium, and low endotoxin stress responsive sheep. M.Sc. Thesis. University of Guelph.

L.C. Kabaroff (M.Sc.) 2005. The acute phase response to *E. coli* LPS in pregnant and non-pregnant ewes. M.Sc. Thesis. University of Guelph.

Evaluation of local and systemic bovine cytokine responses to intramammary challenge with persistent and genetically characterized strains of Staphylococcus aureus. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Toronto, November 3-6.

C. Verschoor, S.D. Pant, B.S. Sharma, F. Schenkel, **N.A. Karrow** 2008. Single nucleotide polymorphisms in type-1 and -2 cytokines are associated with health and production traits in Canadian dairy bulls. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Toronto, November 3-6.

M.M. Or-Rashid, R. Fisher, **N.A. Karrow**, O. AlZahal, B.W. McBride 2008. Fatty acid profile of colostrum and milk of ewes supplemented with docosahexaenoic acid and the subsequent plasma fatty acid status of their lambs. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

M.M. Or-Rashid, R. Fisher, **N.A. Karrow**, O. AlZahal, B.W. McBride 2008. Plasma fatty acid profile of gestating ewes supplemented with docosahexaenoic acid. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

S.D. Pant, C. Verschoor, F.S. Schenkel, B.S. Sharma, **N.A. Karrow** 2008. Identification of single nucleotide polymorphisms in bovine peptidoglycan recognition protein 1 and their association with inflammatory disease resistance in Canadian dairy cattle. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

K. Alain, **N.A. Karrow,** M. Lessard, B.A. Mallard N. Bissonnette 2008. Identification of the osteopontin transcript during the early phases of intramammary infection caused by Escherichia coli and Staphylococcus aureus using subtractive suppressive hybridization. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

S. Cartwright, E.B. Burnside, **N.A. Karrow**, L. Schaeffer, B.A. Mallard 2008. Variation in antibody and cell-mediated immune responses between Canadian Holsteins and Norwegian-Red first calf heifers. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

B.S. Sharma, S.D. Pant, C. Verschoor, F.S. Schenkel, **N.A. Karrow** 2008. Association of Toll-like receptor 4 polymorphisms with Johne's disease. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

A. Skelding, B.S. Sharma, C. Verschoor, S.D. Pant, F. Schenkel, H. Boermans, **N.A. Karrow** 2008. Association of single nucleotide polymorphisms in the interleukin-12 receptor β-2 gene with Johne's disease and production traits in dairy cattle. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

C.P. Verschoor, S.D. Pant, B.S. Sharma, F. Schenkel, and **N.A. Karrow** 2008. Single nucleotide polymorphisms (SNPs) in bovine IL-10, IL-10 receptor, and TGF-®, and their association with milk somatic cell score and susceptibility to *Mycobacterium avium paratuberculosis* (MAP) infection. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

A. Rakhshandeh, **N.A. Karrow**, S.P. Miller, and C.F.M. de Lange 2008. C.F.M. Impact of immune system stimulation and sulfur amino acid intake on urinary sulfur excretion and whole body nitrogen to sulfur balance ratio in pigs. Annual meeting of the Canadian Society of Animal Science. Guelph, Ont., August 11-14.

A. Rakhshandeh, **N.A. Karrow**, S.P. Miller, and C.F.M. de Lange 2008. Impact of immune system stimulation and sulfur amino acid intake on urinary sulfur excretion and whole-body nitrogen to sulfur balance ratio in pigs. Animal Nutrition Association of Canada 44th annual Eastern Nutrition Conference, Guelph, Ont., May 22-23.

S.D. Pant, F.S. Schenkel, C. Verschoor, I. Leyva, B.S. Sharma, **N.A. Karrow** 2007. Identification of polymorphisms in bovine PGRP and CARD15, and associations between

CARD15 polymorphisms and milk somatic cell score in Canadian Holsteins, and functional relevance of SNP c.3020A>T. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Montreal, November 12-13.

C. Verschoor, S. Pant, **N.A. Karrow** 2007. Single nucleotide polymorphisms in the Canadian Holstein IL-10, IL-10 receptor, and TGF-β1 genes. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Montreal, November 12-13.

B.S. Sharma, J. Mount, **N.A. Karrow** 2007. Functional relevance of a promoter single nucleotide polymorphism of the bovine Toll-like-4 receptor gene. International Symposium on Animal Genomics for Animal Health, Oct. 23-25, Paris, France, and Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Montreal, November 12-13.

S.D. Pant, F.S. Schenkel, I. Leyva, B.S. Sharma, **N.A. Karrow** 2007. Identification of polymorphisms in bovine *TLR-2* and *CARD15*, and associations between *CARD15* polymorphisms and milk somatic cell score in Canadian Holsteins. International Symposium on Animal Genomics for Animal Health, Oct. 23-25, Paris, France.

K.A. Phillipps, **N.A. Karrow**, C.M. McNicoll, E. Courtney, J. Hay, and H. Boermans 2007. Use of an ovine model to evaluate the effects of ageing on the acute-phase response. XIth International Congress of Toxicology, July 15-19, Montreal.

Doelman, J., N.G. Purdie, C. Hao, L.E. Wright, **N.A. Karrow**, J.P. Cant 2007. Hepatic gene expression profiling in fasted postpubertal Holstein dairy heifers. ADSA-PSA-AMPA-ASAS Joint Annual Meeting. San Antonio, TX, July 8-12.

Leung, M. C. K., T. K. Smith, **N. A. Karrow**, and H. J. Boermans 2007. Effects of feedborne Fusarium mycotoxins with and without a glucomannan mycotoxin adsorbent on body weight, feed intake, serum chemistry, and nutrient digestibility of mature beagles. ADSA-PSA-AMPA-ASAS Joint Annual Meeting. San Antonio, TX, July 8-12.

R. Fisher, H. Drake, E. Finegan, S. Miller, J. Atkinson, H. Boermans, **N.A. Karrow** 2007. Ovine maternal inflammatory stress during late pregnancy alters offspring febrile responsiveness to systemic endotoxin challenge later in life. 46th Annual Society of Toxicology Meeting, March 25-29, Charlotte, North Carolina.

K.A. Phillipps, **N.A. Karrow**, C.M. McNicoll, E. Courtney, J. Hay, and H. Boermans 2007. Age-related changes in adrenal responsiveness, granulocyte trafficking, and serum IL-6 concentrations in female sheep systemically challenged with *Escherichia coli* lipopolysaccharide. 46th Annual Society of Toxicology Meeting, March 25-29, Charlotte, North Carolina.

Leung, M.C.K., M. K. Brunt, **N.A. Karrow**, H.J. Boermans, S.T. Millman, and T.K. Smith (2006). Nutritional toxicity of feed-borne Fusarium mycotoxins on mature beagle dogs. 42nd Eastern Nutrition Conference, Animal Nutrition Association of Canada. Guelph, ON, Canada, May 11–12.

B.S. Sharma, F. Schenkel, **N.A. Karrow** 2006. Associations of bovine TLR4 with milk somatic cell score and other health traits in Canadian Holstein cows. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Mississauga, Ont., November 15-16.

S. Pant, F. Schenkel, I. Leyva, B.Sharma, **N.A. Karrow** 2006. Identification of single nucleotide polymorphisms in bovine *CARD15/NOD2* and its association with milk somatic cell score in Canadian Holsteins. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Mississauga, Ont., November 15-16.

J. Mount, Y. Kim, **N.A. Karrow** 2006. Assessment of chemokine gene expression in bovine mammary gland tissue explants in response to LPS, LTA+PTG, and CpG ODN2135. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Mississauga, Ont., November 15-16.

I. Leyva, F. Schenkel, B.S. Sharma, G.B. Jansen, **N.A. Karrow** 2006. Evaluation of DNA pooling for low frequency SNP detection, and the association of *CXCR1*+777 SNP with health and production traits in Canadian Holstein bulls. Annual Scientific Meeting of the Canadian Bovine Mastitis Research Network, Mississauga, Ont., November 15-16.

L. Kabaroff, A. Rodriguez, H. Boermans, **N.A. Karrow** 2006. Assessment of the ovine acute phase response to Escherichia coli endotoxin. 45th Annual Society of Toxicology Meeting, March 5-9, San Diego, California.

Q. You, A. Rodriguez, B.A. Mallard, **N.A. Karrow** 2006. Evaluation of immune responsiveness and hepatic gene expression in high (H), middle (M), and low (L) inflammatory stress responsive sheep. 45th Annual Society of Toxicology Meeting, March 5-9, San Diego, California.

H. Drake, H. Boermans, **N.A. Karrow** 2006. Fetal programming of the ovine neuroendocrine-immune system in response to an acute bacterial endotoxin challenge. 45th Annual Society of Toxicology Meeting, March 5-9, San Diego, California.

B.S. Sharma, I. Leyva, D. Kelton and **N. A. Karrow** 2005. Polymorphisms in *TLR4* and their association with health traits in Canadian Holsteins. 3rd International Symposium on Genetics of Animal Health, July 13-15, Ames, Iowa.

Q.M You, A. Rodriguez, B.A. Mallard, **N.A. Karrow** 2005. Evaluation of immune responsiveness in high and low stress responsive sheep. 3rd International Symposium on Genetics of Animal Health, July 13-15, Ames, Iowa.

I. Leyva, B. S. Sharma, G. B. Jansen, and **N. A. Karrow** 2005. Potential associations of single nucleotide polymorphisms located in *CCL2*, *CCR2*, *CXCL8* and *CXCR1* genes with health, production and conformation traits in Canadian Holsteins. 3rd International Symposium on Genetics of Animal Health, July 13-15, Ames, Iowa.

H. Drake, H. Boermans, and **N.A. Karrow** 2005. Fetal programming of the ovine neuroendocrine-immune system in response to an acute bacterial endotoxin challenge. 18th Annual Spring Meeting of the Canadian Society for Immunology, April 7-10, Whistler, BC.

L. Kabaroff, **N.A. Karrow**, and H.J. Boermans 2005. Changes in the ovine hypothalamic-pituitary-adrenal axis during pregnancy and lactation following challenge with *Escheriichia coli* lipopolysaccharide. 44th Society of Toxicology Meeting, March 6-10, New Orleans.

B.S. Sharma, G.B. Jansen, **N.A. Karrow**, and Z. Jiang 2004. Detection and mapping of an AFLP marker for clinical mastitis in Canadian Holsteins. 29th International Conference on Animal Genetics, September 11-16, Tokyo, Japan.

I. Leyva, B.S. Sharma, G.B. Jansen, and **N.A. Karrow** 2004. Association of the single nucleotide polymorphisms from the MCP-1 gene with milk somatic cell counts (SCC) in a Canadian Holstein cattle population. 29th International Conference on Animal Genetics, September 11-16, Tokyo, Japan.

L. Kabaroff, H.J. Boermans and **N.A. Karrow** 2004. Responsiveness of the ovine hypothalamic-pituitary-adrenal axis during pregnancy and lactation following immunological challenge with *Escherichia coli* lipopolysaccharide. 7th International Veterinary Immunology Symposium, July 25-30, Quebec City.

B.A. Mallard, Z. Alizadeh, **N.A. Karrow**. 2003. Biological effect of varying peptide binding affinity to BoLA-DRB3*2703 allele. IVVDC, July 13-18, Guelph, Ont..

B.A. Mallard, W. Tao, **N.A. Karrow**, and B. Bridle 2003. Construction and validation of a bovine immune-endocrine cDNA microarray. IVVDC, July 13-18, Guelph, Ont.
H. V. L. N. Swamy, T. K. Smith, **N.A. Karrow**, and H.J. Boermans. 2003. Effects of feeding blends of grains naturally-contaminated with *Fusarium* mycotoxins on immune parameters of broiler chickens. Poster presented at Annual Meeting of Poultry Science Association, July 6-9, Madison, WI.

H. V. L. N. Swamy, T. K. Smith, E.J. MacDonald, **N.A. Karrow**, and H.J. Boermans. 2003. Effects of feeding blends of grains naturally-contaminated with *Fusarium* mycotoxins on antibody titers and brain neurochemistry of starter pigs. Poster presented at Annual Joint Meeting of American Society of Animal Science and American Society of Dairy Science, June 21-26, Phoenix, AZ.

W. Tao, B.A. Mallard, **N.A. Karrow**, and B.Bridle 2003. Construction and validation of a bovine immune-endocrine cDNA microarray. International Symposium on Animal Functional Genomics. May 9-11, East Lansing, Michigan.

H.V.L.N. Swamy, T.K. Smith, E.J. MacDonald, H.J. Boermans, **N.A. Karrow** and W.D. Woodward. 2002. Effects of feeding blends of grains naturally-contaminated with Fusarium mycotoxins on growth, serum chemistry and haematology of starter pigs. Joint Meeting of the

American Dairy Science Association, American Society of Animal Science, and Canadian Society of Animal Science, July 21-25, Quebec City, Quebec.

B.A. Mallard, Z. Alizadeh, **N.A. Karrow**, B.N. Wilkie and S. Sharif. 2002. Varying peptide binding affinity to BoLA-DRB3*2703. 16th Spring Meeting of the Canadian Society for Immunology, April 5-8, Collingwood, ON.

A. Hernandez, **N.A. Karrow**, B.N. Wilkie and B.A. Mallard. 2002. Evaluation of DTH and antibody to OVA as a means to identify high (H) and low (L) immune responsiveness in cattle: Microarray analysis of gene expression associated with H and L immune response phenotypes. 16th Spring Meeting of the Canadian Society for Immunology, April 5-8, Collingwood, ON.

Z. Alzadeh, **N.A. Karrow** and B.A. Mallard. 2001. Biological effect of varying peptide binding affinity to BoLA-DRB3.2*2703 allele. 6th International Veterinary Immunology Symposium, July 15-20, Uppsala, Sweden.

N.A. Karrow, T.L. Guo, L.X. Zhang, J.A. McCay, V.L. Peachee, R.D. Brown, D.L. Musgrove, C.K. Washington, D.R. Germolec and K.L. White, Jr. 2001. The immunomodulatory effects of thalidomide in B6C3F1 mice after 28 days of treatment: A study of the macrophage phagocytic system and host resistance. 40th Annual Meeting of the Society of Toxicology, San Francisco, California, March 25-29. (The Toxicologist 60, 1)

T.L. Guo, J.A. McCay, L.X. Zhang, **N.A. Karrow**, R.D. Brown, D.R. Germolec and K.L. White, Jr. 2001. Genistein modulates immune responses and increases host resistance to B16F10 tumor model in adult female B6C3F1 mice. 40th Annual Meeting of the Society of Toxicology, San Francisco, California, March 25-29. (The Toxicologist 60, 1)

N.A. Karrow, J.A. McCay, T.L. Guo, G.W. Johnson, R.D. Brown, D.L. Musgrove, D.R. Germolec and K.L. White, Jr. 2000. Exposure to sodium chlorite in drinking water for 28 days produced minimal immunomodulatory effects in female B6C3F1 mice. 39th Annual Meeting of the Society of Toxicology, Philadelphia, Pennsylvania, March 19-23. (The Toxicologist, 54, 1, 157)

T.L. Guo, J.A. McCay, **N.A. Karrow**, G.W. Johnson, R.D. Brown, D.L. Musgrove, D.R. Germolec and K.L. White, Jr. 2000. Exposure to sodium bromate in drinking water for 28 days produced minimal immunotoxic effects in female B6C3F1 mice. 39th Annual Meeting of the Society of Toxicology, Philadelphia, Pennsylvania, March 19-23. (The Toxicologist, 54,1, 156)

J.A. McCay, D.L. Musgrove, R.D. Brown, G.W. Johnson, **N.A. Karrow**, T.L. Guo, D.R. Germolec and K.L. White, Jr. 2000. N.A. Karrow, H.J. Boermans, N.C. Bols, D.G. Dixon, K.R. Solomon and J.J. Whyte. 1997. Characterizing the immunotoxicity of creosote to rainbow trout Oncorhynchus mykiss: a mesocosm study update. CNTC Meeting, March 23-25, Toronto, ON.

N.A. Karrow, H.J. Boermans, N.C. Bols, D.G. Dixon, K.R. Solomon and J.J. Whyte. 1996. Characterizing the immunotoxicity of creosote to rainbow trout Oncorhynchus mykiss: a mesocosm study. SETAC 17th Annual Meeting, November 17-21, Washington, DC.

J.J. Whyte, **N. Karrow**, S. Majdic, D.G. Dixon and N.C. Bols. 1996. Use of SPMDs and rainbow trout to examine CYP1A1 induction in creosote contaminated mesocosms. SETAC 17th Annual Meeting, November 17-21, Washington, DC.

N.A. Karrow, H.J. Boermans, N.C. Bols, D.G. Dixon, K.R. Solomon and J.J. Whyte. 1996. Characterizing the immunotoxicity of creosote to rainbow trout Oncorhynchus mykiss: a mesocosm study. CNTC Meeting, March 23-25, Toronto, ON.

SOCIETY MEMBERSHIPS:

Canadian Society for Animal Science
American Society of Animal Science
International Society for Developmental Origins of Health and Disease
International Society for Animal Genetics

RESEARCH FUNDING:

2023	Mitacs Globalink Research Awarded to Ran Xu $6,000 Role of Peyer's patches in mycotoxicity
2022-2025	$168,000 OMAFRA-Tier 1 Impact of maternal diet on small ruminant colostrum bioactives and postnatal health
2022-2023	$203,166 TrouwNutrition The effects of feeding gestating sows Fusarium mycotoxins and potential mitigation with mycotoxin binders
2021-2023	$210,000 NSERC-Alliance Impact of maternal diet on small ruminant colostrum bioactives and postnatal health
2022-2025	$124,960 The Canada First Research Excellence Fund Food from thought research program: Breeding livestock for climate resilience Co-Investigator Drs. B.A. Mallard, D. Tulpan, A. Canovas
2021-24	$60,000 Ontario Sheep Farmers The impact of maternal diet and stress on small ruminant colostrum bioactives and postnatal health Principal Investigator
2021-22	$22,000 Gartshore Memorial Sheep Research Fund Impact of maternal diet on sheep colostrum bioactives and postnatal health Principal Investigator

2019-2025 $198,000
NSERC-Discovery
Neuroendocrine-immune system programming of zebrafish embryos and larva: Implications for stress resilience, disease resistance and longevity
Principal Investigator

2019-2021 $434,700
The Canada First Research Excellence Fund
Food from thought research program: Breeding livestock for climate resilience
Co-Investigator
Drs. B.A. Mallard, C. Baes, A. Canovas, F. Schenkel

2019-22 $202,879
NSERC-CRD-Alltech
Penicillium and Fusarium mycotoxin assessment using bovine intestinal epithelial cells (IEC) and co-cultured IEC + macrophages, and remediation with yeast mycotoxin binders
Principal Investigator

2019-22 $403,100
NSERC-CRD- Semex
Assessment of genetics of stress resilience in dairy cattle
Principal Investigator

2018-19 $25,000
NSERC-Discovery
Pre- and post-natal programming of the neuroendocrine-immune system: Implications for stress resilience, disease resistance and longevity
Principal Investigator

2018-20 $120,000
MITACS Elevate Postdoctoral Fellowship-Semex awarded to Dr. Ankita Sharma
Assessment and genetics of stress resilience in dairy cattle
Principal Investigator

2017-2018 $50,000
Jiangsu Aomai Bio-tech Company
Effects of deoxynivalenol on the growth performance, immunity and intestinal microflora of weanling piglets
Co-Investigator
Dr. L. Sun, Huazhong Agricultural University, Wuhan, China.

2017-18 $34,600
OMAFRA-HQP awarded to Samantha Dixon
Leveraging transcriptomics and systems biology to understand the genes and metabolic pathways associated with ovine resistance to gastrointestinal nematodes
Co-Investigator
Dr. A. Canovas

2017-2019 $327,900
The Canada First Research Excellence Fund
Food from thought research program: Breeding livestock for climate resilience
Co-Investigator
Drs. B.A. Mallard, C. Baes, A. Canovas, F. Miglior, F. Schenkel

2016-18 $63,000
OMAFRA-HQP awarded to Emma Borkowski
Investigation of immune response of sheep to gastrointestinal nematode infection under Ontario grazing conditions for purposes of identifying genetically resistance animals
Co-Investigator
Drs. A. Peregrine, P. Menzies

2016-17 $149,850
NSERC-RTI
Zebrafish advanced life support system
Co-Investigator
Drs. T. Van Raay, N. Bernier, J. Dawson, G. Van Der Kraak, T. Gillis, S. Ryan

2016-19 $132,500
NSERC-CRD- Semex
Genetic markers and bovine Johne's disease
Principal Investigator

2016-19 $125,000
OMAFRA
Evaluation of immunonutrition in pigs: leucine and n-3 PUFAs
Co-investigator
Dr. L. Huber

2015-17 65,000 EU
Adisseo France
Assessment of nursing piglet and weaner pig health during selenium supplementation
Co-investigator

Drs. H. Liu and L. Sun, Huazhong Agricultural University, Wuhan, China.

2015-16 $149,900
NSERC-RTI
Purchase of an imaging multi-mode reader for Animal Biosciences research
Co-Investigator
Drs. J. Squires, J. Li, G. Bedecarrats, J. Cant

2015 $17,640 USD
Alltech Inc.
Risk assessment modeling of mycotoxin interactions based on assessment of biomarkers and mycotoxin metabolites, and evaluation of the impact of remediation strategies using zebrafish as an in vivo experimental model
Principal Investigator

2015-18 $332,644
OMAFRA/ OSMA-AAFC- Agri-innovation
Investigation of immune response of sheep to gastrointestinal nematode infection
Co-Investigator
Drs. P. Menzies, A. Peregrine

2015-19 $124,000
Teagasc Walsh Fellowship awarded to Sanjay Mallikarjunappa
Defining Innate Phenotypes Associated with Enhanced Immunity to Johne's Disease
Co-Investigator
Drs. K. Meade, B.A. Mallard, B. Plattner

2015-2019 $440,000
NSERC-CRD- Alltech Inc.
The benefits of algae meal supplementation during pregnancy on piglet and weaner pig health
Principal Investigator

2014-17 $175,000
OMAFRA
Assessing the bioactivity of immune-related microRNAs in colostrum and milk from high and low immune responder cows on intestinal epithelial cells
Co-Investigator
Dr. B.A. Mallard

2014 $27,900
NSERC Engage Plus- Lallemand Inc.
Assessing the immunomodulatory properties of yeast using primary intestinal epithelial cells and bovine macrophages.

Principal Investigator

2014-18 $60,000
Swine Innovation Porc: Canadian Swine Research & Development Cluster 2
Innovative piglet management strategies for optimum performance up to slaughter weight and profitable pork production
Co-Investigator
Drs. C.F.M. De Lange and J. Squires

2014-17 $225,000
NSERC-CRD- Dairy Farmers of Ontario
Assessing the bioactivity of bovine colostrum and milk immune-related miRNAs from high and low immune responder cows on human IECs
Principal Investigator

2013-16 $187,082
NSERC CRD- Canadian Dairy Network
Genetic hallmark of susceptible cows through macrophage profiling of MAP infected cows
Co-Investigator
Dr. N. Bissonnette

2013-2015 $115,000
MITACS Elevate Postdoctoral Fellowship-Alltech Inc. awarded to Dr. Rebecca Fisher
The benefits of algae meal supplementation during pregnancy on piglet health
Principal Investigator

2013-2015 $43,750
Ontario Sheep Marketing Agency-OFIP Growing Forward 2
Maedi-Visna in sheep and potential interaction with *Mycobacterium avium spp. paratuberculosis*
Principal Investigator

2013-14 $42,700
Alltech Inc.
Immunomodulatory effects of Penicillium mycotoxins
Principal Investigator

2013-14 $30,000
MITACS-Accelerate Internship Program awarded to Ziwei Li
Identification and assessment of bioactive yeast strains and cell wall components
Principal Investigator

2013-16	$68,000 OMAFRA-HQP awarded to Nancy Stonos Vaccine response of acutely stressed high, medium and low cortisol response sheep Principal Investigator
2013-19	$169,000 NSERC-Discovery Genetic and epigenetic regulation of the stress response and implications for ruminant health Principal Investigator
2013	$24,000 NSERC Engage- Lallemand Inc. Assessing the immunomodulatory properties of probiotics using intestinal epithelial cells and bovine macrophages. Principal Investigator
2012	$24,500 NSERC Engage- Ontario Goat Prevalence of CAEV in Ontario goat herds Principal Investigator
2012-14	$86,000 NSERC CRD- Ontario Pork Robustness of starter pigs Co-Investigator Dr. C.F.M. De Lange
2012	$7,500 Gartshore Memorial Sheep Research Fund Impact of dietary fatty acids on fetal development Principal Investigator
2010-12	$80,000 MITACS Elevate Postdoctoral Fellowship-Alltech Inc. awarded to Dr. Bhawani Sharma Epigenetic programming and Penicillium mycotoxins Principal Investigator
2010-11	$7,950 OMAFRA Appropriate welfare considerations for sheep subject to the recto-anal mucosa associated lymphoid tissue biopsy for detection of scrapie infection Co-Investigator Dr. Paula Menzies

2010-13 $210,000
NSERC CRD- Canadian Dairy Network. Dairy Farmers of Ontario
Breed-specific gene expression profiles and DNA methylation patterns in calves infected with Mycobacterium avium subsp. paratuberculosis (MAP)
Principal Investigator

2010-11 $50,000
OMAFRA
Mycotoxins and the developing neuroendocrine-immune system
Principal Investigator

2009-12 $64,267
OMAFRA HQP awarded to Steven Oh
Effect of Penicillium mycotoxins on the development of ruminant neuroendocrine-immune system
Principal Investigator

2009-12 $232,998
NSERC CRD-Canadian Dairy Network
Applied genetic and epigenetic influences on high and low immune response phenotypes of dairy cattle
Co-Investigator
Dr. B.A. Mallard

2008-9 $103,000
NSERC CRD- Canadian Dairy Network
High and low immune response phenotypes: genes and proteins associated with health and performance
Co-Investigator
Dr. B.A. Mallard

It's not yet clear whether antibodies in the blood of patients who have been infected with SARS-CoV-2 indicate immunity. Above: blood specimens for COVID-19 antibody tests. (AP Photo/Mary Altaffer)

Can antibody tests tell us who is immune to COVID-19?

Published: May 26, 2020 12.17pm EDT

Shayan Sharif
Professor of Immunology and Associate Dean, Research and Graduate Studies, University of Guelph

Byram W. Bridle
Associate professor, Department of Pathobiology, University of Guelph

Widespread media coverage of antibody testing for SARS-CoV-2, the virus that causes COVID-19, has generated high hopes that we will be able to readily identify individuals who are immune to this virus.

There has also been coverage about developing immunity passports, which employers can use to let people return to work. While these are all tantalizing thoughts, the idea of using antibody testing as a true measure of protection is something that requires much more research.

As immunologists, our interest is in understanding how the immune system responds to viruses, especially zoonotic viruses that can be transmitted from animals to humans, like SARS-CoV-2. Here, we share our insights into different aspects of antibody testing, including its promises as well as caveats.

Immune response to a new pathogen

Colourized scanning electron micrograph of a cell (red) from a patient sample, heavily infected with SARS-CoV-2 virus particles (yellow). (National Institute of Allergy and Infectious Diseases)

An emerging zoonotic pathogen — such as SARS-CoV-2 — is unique in the sense that humans have never been exposed to it, so our immune system has never mounted a response to this specific virus. When we are exposed to an emerging pathogen, our immune system mounts different types of responses within seven to 14 days.

Antibodies are one type of response: they are secreted into the blood and, more importantly, are present at sites of infection. In the case of SARS-CoV-2, antiviral antibodies can be found in the blood after infection, but they are also presumably present in the respiratory system, where the virus resides and propagates.

Although the presence of antibodies in an individual confirms that an infection has occurred, antibodies alone cannot differentiate between a historical versus current infection.

Antibody tests

Several companies have begun producing antibody testing kits, some of which have received regulatory approval. Currently, Health Canada has approved only one antibody test. The U.S. Food and Drug Administration has issued emergency use authorization for 12 tests, including a combination of lab-based and point-of-care tests, while 200 other devices are awaiting approval.

A registered nurse draws blood for a COVID-19 antibody test in the Harlem neighbourhood of Manhattan on May 14, 2020. Testing drives through churches in low-income communities across New York are offering COVID-19 testing to residents. (AP Photo/Mary Altaffer)

Large-scale antibody testing has already been performed in parts of the U.S. and Europe. For example, in Chelsea, Mass., 64 out of 200 people in the downtown area tested positive for COVID-19 exposure using antibody testing. Other areas have also reported high prevalence of antibody response to SARS-CoV-2, including 25 per cent in New York City, approximately 2.8 per cent in Santa Clara County, Calif., and 14 per cent in Gangelt, Germany.

While these data imply that significantly more people have been exposed to or infected with SARS-CoV-2 than have been diagnosed using nucleic acid-based tests, these antibody-positive people may not be immune to SARS-CoV-2.

Are people who have had COVID-19 immune?

Depending on the type of virus, antibodies in the blood may or may not confer protection against the virus. We can only hope that the antibodies circulating in the blood of patients infected with SARS-CoV-2 are good indicators of protection.

Read more: Know your target: Fundamental science will lead us to coronavirus vaccines

However, there is a chance that there is only a weak connection, or no connection at all, between antibody presence in the blood and protection against SARS-CoV-2. This is because antibodies in the blood will have to find their way to the respiratory system — where the virus resides — to exert their protective functions. Sometimes they do not end up in the lungs where they are most needed for protection. Also, these antibodies may not be of the right type to protect against infection or there may not be enough of them present to establish protection.

A 3D print of a spike protein of SARS-CoV-2, the virus that causes COVID-19, in front of a 3D print of a SARS-CoV-2 virus particle. The spike protein (foreground) enables the virus to enter and infect human cells. On the virus model, the virus surface (blue) is covered with spike proteins (red). (NIH)

It is speculated that protective antibodies bind to the molecular structures on the surface of SARS-CoV-2, especially its spike protein. The spike proteins are the points that cover the surface of the virus, forming the "crown" that gives coronaviruses their name. The virus uses these spikes to attach to cells of the respiratory system. The antibodies that bind to SARS-CoV-2's spike protein may prevent the virus from attaching to cells. Viruses that are not able to attach and enter a cell cannot propagate and will eventually die out.

It is safe to say that antibody testing is an excellent way to determine whether there has been exposure to the virus, but not necessarily whether protection has been established. That presents a potential danger in rushing the concept of immunity passports into use: people with positive antibody tests may behave as though they are protected against COVID-19 when, in fact, they may not be.

How can we test for immunity?

Given what we now know, can we conceivably use antibody testing as a measure of immunity? The answer is maybe! If one looks at other more familiar respiratory viruses, like influenza viruses, there is usually good correlation between antibodies in the blood and protection against influenza virus.

A sign listing COVID-19 tests available, including an antibody test, on April 28, 2020, in Houston, Texas. (AP Photo/David J. Phillip)

What needs to happen now is a series of epidemiological studies looking at people with high and low concentrations of antibodies to determine whether the presence of antibodies is associated with protection against re-infection with SARS-CoV-2 and if so, what is the minimum quantity of antibodies for conferring protection.

This process will take some time, but it is very doable. One way to speed up the process is to develop tests to assess antibodies for their potential to prevent SARS-CoV-2 infection. Using antibodies taken from the respiratory systems of individuals who have been infected, these tests would see if those antibodies could prevent the virus from infecting susceptible cells in a culture dish.

Simultaneously studying antibodies in the blood of these same individuals would then tell us how well the current "quick and easy" antibody tests correlate with the antiviral functions of the antibodies in the respiratory system.

On April 23, 2020, Prime Minister Justin Trudeau announced the formation of the COVID-19 Immunity Task Force to "... oversee the co-ordination of a series of country-wide blood test surveys that will tell us how widely the virus has spread in Canada and provide reliable estimates of potential immunity and vulnerabilities in the Canadian population."

What T cells can tell us

A scanning electron micrograph of a healthy human T-cell. (NIAID)

If it turns out that antibody tests can confirm exposure but do not indicate immunity, there are alternative approaches to immunity testing. One of the main players in immunity against viruses is a subset of cells called T-cells. These cells have an enormous capacity to recognize and respond to viruses by killing the virus-infected cells.

We have limited understanding of the involvement of T-cells in immunity against SARS-CoV-2, but it is possible that these cells play a pivotal role in protection. The question is whether we can use T-cell responses as indicators of immunity. The answer is both yes and no.

While it is feasible to measure T-cell responses in laboratory settings, it is time-consuming and requires a level of technical sophistication that is not available in most diagnostic labs. Also, T-cell testing will have to be done as a high-throughput procedure, meaning that a large number of samples is tested at once. Although high-throughput testing has not been fully developed for diagnostic purposes, the technology is there, so T-cell testing may play a role in assessing immunity to SARS-CoV-2.

This pandemic has been a true test for science and scientists. Studying our immune response to SARS-CoV-2 may not only be the key to identifying who is protected from the virus, but also to developing potential vaccines and treatments.

The scope and length of vaccine testing experiments usually mean decade-long timelines for development. (Pixabay)

Fast COVID-19 vaccine timelines are unrealistic and put the integrity of scientists at risk

The average times of the fastest sprinters in the 100-metre dash are in the ballpark of 10 seconds. So, what would you think if someone promised to run the race in one second?

It typically takes a minimum of 10 years for a vaccine to complete the three consecutive phases of the clinical research pipeline. This is because of the scope and length of the experiments, the need to critically assess the results at each stage and the mountains of paperwork that are involved.

What are the chances that this can be reduced to 12 months? Indeed, it has been implied that this process can be accelerated to "warp speed."

It usually takes about 10 years to develop and test a new vaccine. (Shutterstock)

We contend that a safe and effective vaccine against severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2), which is the causative agent of coronavirus disease COVID-19, most likely cannot be made available to the public in time to make a substantial difference to the natural outcome of this pandemic. People often cling to hope even when prospects of success are low. However, this can have negative consequences if that hope is not realized.

We are academic scientists who manage vaccine research programs. In fact, Dr. Bridle received COVID-19-focused funding to develop a novel vaccine platform. Although many of us are working hard towards developing vaccines against SARS-CoV-2, we worry that some in the scientific community have offered too much hope for this to be accomplished in a timely fashion. Sometimes these promises are used by politicians and governments to inform public policies. As a result, the integrity of the scientific community is now in the limelight and, arguably, at risk.

Herd immunity

Vaccines are an effective way for a population to achieve what is known as "herd immunity." This is the concept that the pandemic will end once approximately 60-70 per cent of people become immune to SARS-CoV-2. An alternative is to let SARS-CoV-2 run its natural course until herd immunity is achieved. With physical distancing, some epidemiologists argue this could take two years, during which time a vaccine could be developed.

Social and physical distancing signs on the floors of various business throughout Vancouver and surrounding area are pictured between May 1-12, 2020. THE CANADIAN PRESS/Jonathan Hayward

However, vaccinating at the tail end of a pandemic when disease incidence is very low and declining may be of little utility, hence the race to develop a vaccine for COVID-19. If one is not in widespread use within the first half of 2021, it will probably be too late to have a meaningful impact on control of COVID-19.

Lessons from SARS and MERS

Educators often rely on past performance to predict the future performance of students. In this respect, how was the performance of the scientific community in the wake of the original SARS-CoV, or Middle East respiratory syndrome (MERS)-CoV? The fact is, no vaccine against a coronavirus has successfully navigated the rigours of clinical testing, despite having up to 17 years to do so.

The same applies to other dangerous respiratory pathogens, such as respiratory syncytial virus. Whether enough has been learned from these past experiences to get the design of COVID-19 vaccines right remains to be seen, and still does not negate the need for a rigorous testing process that will take time.

3D print of a spike protein of SARS-CoV-2 in front of a 3D print of a SARS-CoV-2 virus particle. The spike protein (foreground) enables the virus to enter and infect human cells. On the virus model, the virus surface (blue) is covered with spike proteins (red) that enable the virus to enter and infect human cells. (U.S. National Institutes of Health)

One concern is that some vaccines can protect against disease (that is, the outcome of an infection) but not against infection (the ability of the virus to get into the body). In this scenario, vaccinated individuals could potentially become asymptomatic carriers of SARS-CoV-2, thereby spreading COVID-19. For this and many other reasons, a cautious approach must be taken to developing COVID-19 vaccines.

Vaccines already in clinical trials

What about the fact that there are front-runner vaccines already in human clinical trials? First, many of the vaccine technologies that can most readily make it to the front of the line are not necessarily the best quality. The easiest way to make a vaccine is to inactivate the pathogen or use pieces of it, and mix them with an adjuvant, which tells the immune system that the pathogen is dangerous and worth responding to.

Illustration of coronavirus structure. (Pixabay)

However, an inactivated virus or its components do not behave like the live virus, so the immune system sometimes responds to these vaccines in a way that is ineffective or sometimes even dangerous. For example, no vaccine based on the genetic material, known as ribonucleic acid or RNA, from a virus like SARS-CoV-2 has ever been approved. Further, some vaccines developed against the original SARS-CoV, after the epidemic was over, exacerbated the disease in mice.

A vaccine for COVID-19 does not have to be the best one, but it does need to be good enough to accelerate a population's progression to herd immunity. As experienced peer reviewers, we have some concerns about the rigour of some of the science surrounding COVID-19 vaccines.

Some vaccines are fast-tracking through the regulatory system before studies are completed and with minimal details of experimental results being released. Executives of a big pharmaceutical company whose vaccine is among those closest to the finish line recently sold their stocks after releasing "positive results" that were superficial, partial and that included three of eight healthy young volunteers experiencing severe adverse events.

Events like this are causing the public to become skeptical. A promising vaccine should have solid data to back it up. Those touting vaccines against COVID-19 that are in clinical trials should be asked to provide comprehensive details and results of their study. This enables objective and rigorous evaluations by the broader scientific community. A lack of complete transparency would be cause for concern.

Getting from trials to clinics

Assuming a vaccine succeeds in human trials, it then needs to be manufactured in massive quantities at an affordable price, undergo quality control testing and be distributed worldwide. Even if by some miracle this spectrum could be bridged at warp speed, one then needs to wonder if up to 70 per cent of individuals can be effectively vaccinated.

Once a vaccine is developed and approved, it would have to be mass manufactured and distributed before people could get the shot. (Pixabay)

Uptake of a vaccine could be compromised by anti-vaxxers, as well as by perceptions that warp-speed manoeuvring might be the result of cutting too many corners and compromising safety. Then there are those who simply do not respond as well to vaccines, which includes the elderly who are in the greatest need of protection.

Considering what we now know about SARS-CoV-2 vaccines, we need to take a more cautious approach and one could question if any of the vaccines that are now in pre-clinical testing can possibly help with the current pandemic. We sincerely hope that our pessimism about vaccines currently in clinical trials being ready in time is soundly proven wrong.

Even if a vaccine doesn't get developed in time, not all is lost. The array of vaccines being engineered will help with outbreaks beyond COVID-19. They can be vetted by scientists and the best technologies and associated research teams could be shortlisted to be called upon for future outbreaks. Although clinical research likely cannot be shortened to 12 months while maintaining integrity of the science, the current attempt to do so will build new and reasonable efficiencies into health regulatory policies. This will facilitate getting a wide variety of future health solutions to patients faster, but not at warp speed.

THE CONVERSATION

Academic rigour, journalistic flair

Vaccinologists have not focused their research on tailoring vaccines to induce robust immune responses in the elderly. (Shutterstock)

Why vaccines are less effective in the elderly, and what it means for COVID-19

Published: July 20, 2020 3.43pm EDT

Byram W. Bridle
Associate Professor of Viral Immunology, Department of Pathobiology, University of Guelph

Shayan Sharif
Professor of Immunology and Associate Dean, Research and Graduate Studies, University of Guelph

As the global spread of severe acute respiratory syndrome coronavirus (SARS-CoV-2) — the cause of COVID-19 — continues, we learn more about the effects of this new virus.

For many respiratory pathogens, including influenza viruses and respiratory syncytial viruses, the elderly experience the most severe forms of disease and the highest death rates. For example, for every 10,000 Americans between 18 and 49 years old, only 0.4 people die from the annual flu. That number increases to 5.9 people per 10,000 for those aged 65-74 years, and 47.5 people for those over 74 years old. However, most of these diseases can also have a predilection for causing severe disease in the very young.

In this respect, COVID-19 is very different. Data from relatively early in the COVID-19 pandemic showed a dramatic difference in the rates of age-associated deaths, with a case fatality rate of 4.5 per cent for patients ages 60 and older versus only 1.4 per cent for those under 60 years old, with those under 30 years ranging from zero to 0.19 per cent.

Immunosenescence

We are immunologists with research programs devoted to developing vaccines. With COVID-19 placing a spotlight on the elderly as the age demographic most in need of a vaccine, we have felt compelled to evaluate how well scientists are doing at tailoring immunization strategies for this population. Our conclusion is that vaccinologists, ourselves included, have largely failed to focus their research on tailoring vaccine technologies to induce robust immune responses in the elderly.

A critical factor that makes the elderly more susceptible to infectious diseases is what immunologists call "immunosenescence": the decline in the immune system's functionality as people age. This is also associated with an increase in the incidence of inflammatory diseases, because an elderly body tends to be in a state of chronic low-grade inflammation. This "inflamm-aging" is one reason why older people have tendencies to develop more severe forms of respiratory diseases.

Older people have a diminished responses to vaccinations because of immunosenescence. (Pexels/Retha Ferguson)

The key problem with SARS-CoV-2 infection is inflammation in the respiratory tract, which can be exacerbated in individuals predisposed towards potent inflammatory responses.

Immunosenescence also results in diminished responses to vaccination. Indeed, annual flu vaccines are notoriously less effective in the elderly. This phenomenon is very important in the context of the massive efforts and funds being invested worldwide into the ultra-rapid development of vaccines for COVID-19.

The fact that elderly people do not respond well to immunizations has largely been ignored in most discussions of COVID-19 vaccines, despite this being the group in greatest need. Most of the scientific community's experience with vaccine development for any disease has been focused on vaccinating the relatively young.

Young mice and elderly humans

Here is an interesting exercise for people reading this article: find as many original research articles as you can on the topic of vaccine development that have used animal models (it could be for any disease). Then look in the subsection of the "materials and methods" section and check the age of the animals. We were shocked by what we found.

Mice are the most common animals used in preclinical vaccine research and the overwhelming majority of these are 12 weeks old or younger. This is equivalent to people 20 years old and younger. It is comparatively much rarer for studies to use immunosenescent mice that are at least 18 months old and equivalent to an elderly human.

Translational studies that take promising preclinical discoveries and move them towards clinical trials often use non-human primates such as Rhesus macaques. In the majority of cases these are around three to six years old, which is equivalent to an adolescent or young-adult human. The same trend applies to all other animals used in vaccine research.

Early-phase clinical trials focus on safety, not efficacy of vaccines. Therefore, far too many vaccines never get tested in the context of aged immune systems until Phase 2 and 3 clinical trials. The time to find out that a vaccine does not work well in the context of immunosenescence is not at this extremely late stage, when it is too late to fix the problem. This testing should begin in the preclinical phase where an iterative process can be followed to tailor a vaccine for a senescent immune system.

The gloved hand of a lab worker holding a C57BL/6 mouse, a type commonly used in research.
A C57BL/6 mouse. (Shutterstock)

Interestingly, many commercial suppliers of animals that are purpose-bred for research do not have adequate inventories of old animals. Of concern, most old mice that are readily available are of the C57BL/6 strain. This is the most common strain used in research, and is known to have an immune system with a strong bias towards effective responses against viruses.

Intriguingly, aged mice experience a more severe form of SARS after infection, akin to elderly humans. The excessive use of young mice with immune systems that are optimal for antiviral responses, and that experience less severe disease, could bias results in a way that overestimates the potential of vaccines to perform well in the elderly.

Developing vaccines for a key demographic

People age 65 and over suffer the most severe cases of COVID-19 and have the highest associated mortality rate. If the goal is to have COVID-19 vaccines ready for public use by early 2021, the only ones that have a chance are those that are currently in clinical trials. It is likely that most of these did not undergo preclinical optimization for an elderly population, meaning these first-generation COVID-19 vaccines may perform poorly in the people that need them most.

For the COVID-19 pandemic, it is too late to go back and build these considerations into preclinical testing. However, it is imperative that researchers still in the preclinical phase incorporate head-to-head testing of their vaccine candidates in young versus aged animals and develop strategies to optimize them in the latter. This will help the world prepare for the next outbreak of a dangerous coronavirus.

For that matter, a focus on the elderly should be incorporated into other vaccine development programs, including those to treat cancers, which have the highest incidence in older people.

There are viable strategies to improve the effectiveness of vaccines in older people, including changes in formulations, doses and routes of administration. However, it takes substantial time and appropriate animal models to conduct this research. It is possible that the elderly may need fundamentally different vaccination regimens than younger people.

Although a few researchers do conduct vaccine studies in old animals, considerations for the elderly need to be adopted by far more vaccinologists. This is of growing importance for countries with aging populations. This will mean changing the current philosophy of the field of vaccine development and incorporating age as a critical variable.

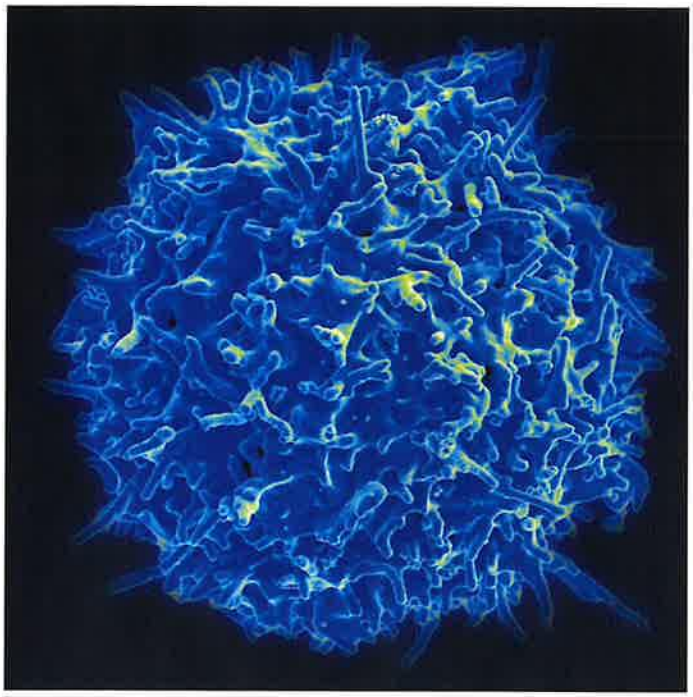
Les athlètes savent qu'il existe deux approches différentes pour entraîner leur corps. En soulevant des poids lourds, ils peuvent arriver à atteindre une force maximale. En revanche, la musculation avec de faibles charges, mais un nombre élevé de répétitions est idéale pour développer la résistance nécessaire aux sports d'endurance.



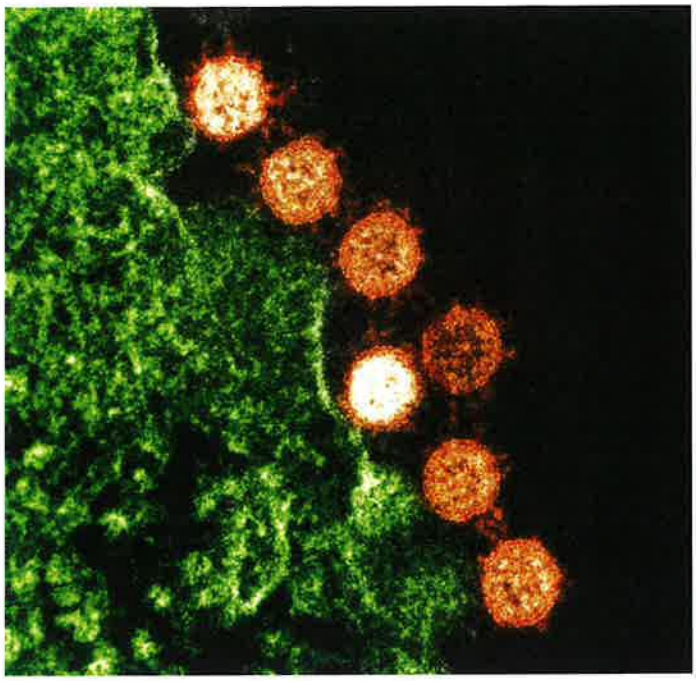
Microscopie électronique à balayage d'un lymphocyte T humain (aussi appelé cellule T) provenant du système immunitaire d'un donneur sain. NIAID, CC BY

Il existe également deux façons d'entraîner notre système immunitaire. Ce dernier peut répondre à des pathogènes dangereux de deux manières, chacune générant une attaque de l'agent infectieux par les anticorps et les globules blancs appelés lymphocytes T. Toutefois, le type de cellules T et d'anticorps diffère selon que l'agent pathogène se trouve à l'extérieur de nos cellules, comme c'est le cas pour de nombreuses bactéries, ou à l'intérieur de nos cellules, comme pour les virus.

La production d'une réaction antibactérienne n'est pas forcément le moyen idéal pour venir à bout d'une infection virale. En fait, une mauvaise réponse immunitaire peut même exacerber la maladie, comme cela a été observé chez des souris vaccinées atteintes du coronavirus du syndrome respiratoire aigu sévère (SARS-CoV), identifié en 2003.

Notre première exposition à un agent pathogène, qu'elle se fasse naturellement ou par la vaccination, peut entraîner notre système immunitaire à adopter l'un de ces deux mécanismes lorsque nous entrerons en contact avec le même agent pathogène ou un agent similaire pour le reste de notre vie. Les immunologistes appellent cela « la mémoire immunitaire entraînée ».

Première exposition



Microscopie électronique en transmission colorisée du coronavirus qui a causé l'épidémie de syndrome respiratoire aigu sévère (SARS) de 2003. Particules virales oranges en bordure d'une cellule infectée verte. (NIAID), CC BY

Nos programmes de recherche couvrent les domaines de la transmission virale, des réponses immunitaires aux virus, des agents pathogènes respiratoires tels que les virus de la grippe et de la conception de vaccins, notamment contre le SARS-CoV-2, qui est responsable de la Covid-19.

Nous aimerions souligner l'importance de l'immunité entraînée en lien avec les vaccins contre la Covid-19, car elle peut avoir des implications sur la capacité de notre système immunitaire à réagir de manière appropriée aux coronavirus hautement pathogènes futurs.

Microscopie électronique à transmission colorisée montrant le coronavirus du syndrome respiratoire du Moyen-Orient (SRMO) qui est apparu en 2012. NIAID, CC BY

Au cours des 17 dernières années, on a vu éclore trois grandes épidémies de coronavirus hautement pathogènes : d'abord le SARS-CoV en 2003, ensuite, le coronavirus du syndrome respiratoire du Moyen-Orient en 2012 et maintenant, le SARS-CoV-2. Si on se base sur le fait qu'un nouveau coronavirus hautement pathogène survient environ tous les dix ans, nous devrions nous attendre à voir apparaître d'autres virus de ce type à l'avenir. Cela signifie que la campagne actuelle de développement de vaccins contre la Covid-19 devrait tenir compte de futures épidémies.

La façon dont nous montrons aujourd'hui à notre système immunitaire à réagir au SARS-CoV-2 pourrait influencer la réponse de notre corps à de futurs coronavirus. Les vaccins, s'ils sont bien conçus, offrent la possibilité d'induire un type d'immunité entraînée optimale pour déclencher des réponses immunitaires protectrices, non seulement contre le SARS-CoV-2, mais aussi contre de futures infections par des coronavirus.

Protection contre la tuberculose

Certains scientifiques ont proposé d'exploiter le concept d'immunité entraînée dans un contexte similaire. Plus précisément, des éléments indiquent que les personnes ayant reçu un vaccin contre la tuberculose pourraient être partiellement protégées contre le SARS-CoV-2.

Microscopie électronique à balayage de la bactérie Mycobacterium tuberculosis. NIAID, CC BY

La tuberculose est une maladie respiratoire causée par une bactérie. Contrairement à de nombreuses bactéries, celle-ci vit à l'intérieur des cellules tout comme les virus. La formule du vaccin utilise une bactérie vivante, mais atténuée (affaiblie), et très semblable à celle qui provoque la maladie. Comme il s'agit d'une bactérie vivante, elle peut infecter les cellules de la même manière que la bactérie de la tuberculose.

Il en résulte une réponse immunitaire appropriée, du même type que celle qui est optimale contre les virus. Les scientifiques en ont conclu que le vaccin contre la tuberculose pourrait entraîner le système immunitaire de manière à ce qu'il puisse réagir de façon idéale à d'autres agents pathogènes qui vivent à l'intérieur des cellules, comme le SARS-CoV-2.

Évaluation des réponses

Microscopie électronique à transmission colorisée du SARS-CoV-2, le virus qui cause la Covid-19.. NIAID, CC BY

Les chercheurs mettent l'accent sur les aspects quantitatifs des vaccins candidats contre la Covid-19, notamment en calculant le nombre d'anticorps générés. Un peu partout, des organismes de réglementation en santé s'apprêtent à approuver des vaccins contre la Covid-19 qui réduisent la charge de morbidité, mais n'engendrent pas une immunité qui préviendrait complètement l'infection et la transmission. Mais ils doivent être prudents et veiller à ce que ces vaccins n'entraînent pas notre système immunitaire à avoir une réaction non optimale.

En évaluant de manière approfondie la nature et la durée de la réponse immunitaire induite par un futur vaccin contre la Covid-19, nous pouvons obtenir des réponses ciblées, efficaces et durables. Concrètement, les développeurs de vaccins devraient tenir compte de ces questions :

1. Le vaccin a-t-il induit une réponse immunitaire optimale contre les virus ? Une réponse antivirale équilibrée devrait comprendre des anticorps pour empêcher le virus d'infecter les cellules hôtes et de se répliquer à l'intérieur de celles-ci ainsi que des lymphocytes T pour tuer les virus qui passent la barrière des anticorps. Il est important que les anticorps soient du type antiviral.

2. Y a-t-il eu des réponses d'anticorps dans les voies respiratoires, et ces anticorps neutralisent-ils efficacement le virus ? On s'attache beaucoup à mesurer les anticorps dans le sang, mais le SARS-CoV-2 infecte la surface des muqueuses, dont celle des voies respiratoires, et il est essentiel de s'assurer que le vaccin induit des anticorps à ces endroits précis. De plus, il faut noter que les réponses des anticorps appropriées contre les virus sont généralement d'une ampleur bien moindre que celles dirigées contre les bactéries extracellulaires. Une grande quantité d'anticorps peut sembler un résultat prometteur, mais c'est loin d'être aussi important que le type et l'emplacement de ceux-ci.

Le message à retenir est que nous devrions insister sur le maintien d'exigences très élevées pour un vaccin contre la Covid-19 — il devra induire une réponse immunitaire appropriée sur le plan qualitatif et qui nous protégera contre l'infection par le SARS-CoV-2.

Comme un athlète, nous devons éviter de former notre système immunitaire d'une manière qui va à l'encontre de l'objectif final. Pour une vision à long terme de notre santé, il faut que notre système immunitaire soit entraîné de manière à déclencher une réponse des plus efficaces possible contre de futurs coronavirus hautement pathogènes, dont certains pourraient s'avérer plus dangereux que le virus actuel.

Training our immune systems: Why we should insist on a high-quality COVID-19 vaccine

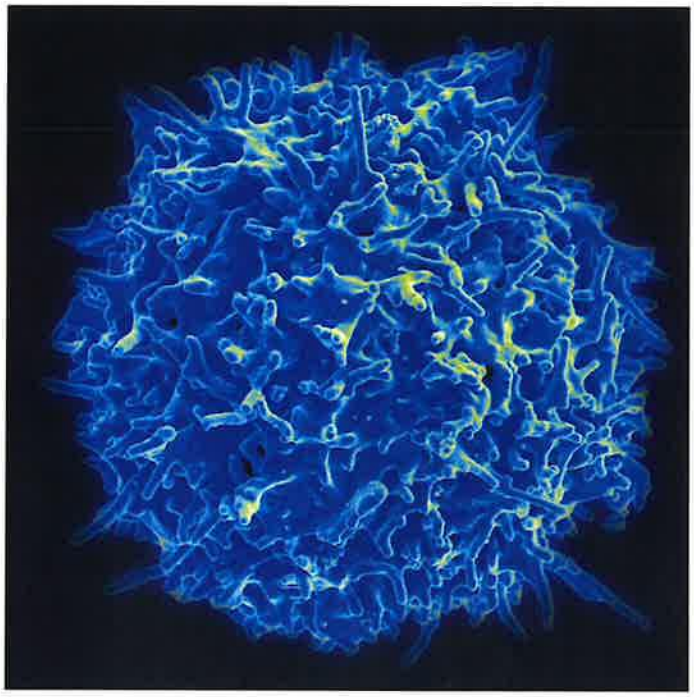
Athletes understand that there are two very different approaches that can be taken when training their bodies. For example, lifting heavy weights is a great way to achieve maximum strength. In contrast, low-load high-repetition training is ideal for developing the stamina required for endurance sports.



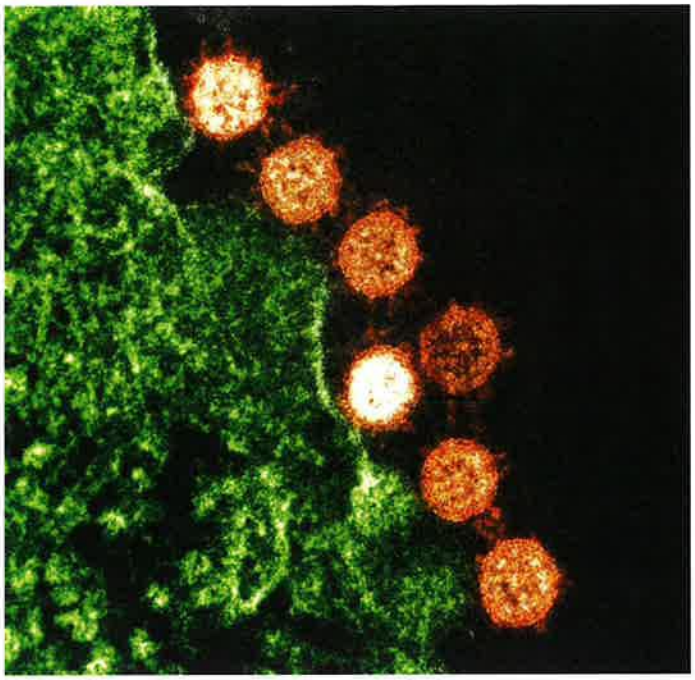
Scanning electron micrograph of a human T lymphocyte (also called a T cell) from the immune system of a healthy donor. (NIAID), CC BY

Remarkably, our immune system can be trained in a somewhat similar fashion. It must choose between two different responses to dangerous pathogens, both of which lead to white blood cells called T cells and antibodies targeting the infecting microbe. However, the types of these T cells and antibodies is different depending on whether the pathogen lives outside of our cells, as many bacteria do, or inside our cells, as viruses do.

Mounting an anti-bacterial response against a virus may not be an ideal way to clear a viral infection. In fact, the wrong kind of immune response can actually exacerbate disease, as was observed in vaccinated mice challenged with the severe acute respiratory syndrome coronavirus (SARS-CoV) identified in 2003.

Importantly, our first exposure to a pathogen, either naturally or via vaccination, can train our immune system to adopt one of these two biases when we respond in the future to the same or a similar pathogen for the rest of our lives. Immunologists call this "trained immunity."

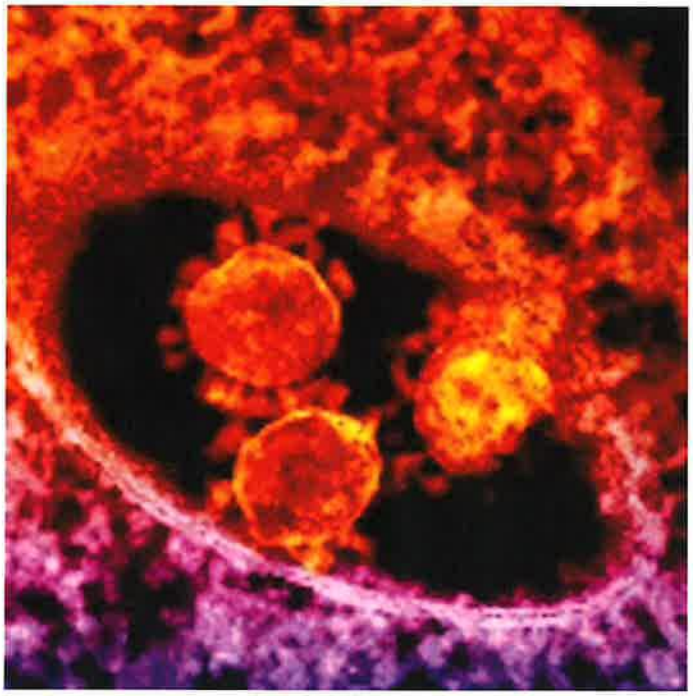
First exposure



Colourized transmission electron micrograph of the coronavirus that caused the 2003 severe acute respiratory syndrome (SARS) outbreak. Orange virus particles at the edge of a green infected cell. (NIAID), CC BY

Our research programs span the fields of viral transmission, immune responses to viruses, respiratory pathogens such as influenza viruses and vaccine development, including vaccines against SARS-CoV-2, which is the causative agent of the coronavirus disease that emerged in 2019, COVID-19.

We would like to convey the importance of trained immunity in the context of COVID-19 vaccines since this can have implications for the ability of our immune systems to respond appropriately to highly pathogenic coronaviruses in the future.



Colourized transmission electron micrograph showing Middle East respiratory syndrome (MERS) coronavirus that emerged in 2012. (NIAID), CC BY

Over the past 17 years, there have been three major outbreaks of highly pathogenic coronaviruses: the original SARS-CoV in 2003, Middle East Respiratory Syndrome coronavirus in 2012 and now SARS-CoV-2. Based on this history of having a new highly pathogenic coronavirus emerge approximately every decade, we should expect to have to deal with more of these viruses in the future. That means that the current drive to develop vaccines for COVID-19 should consider future coronavirus outbreaks.

The way we train our immune systems now to respond to SARS-CoV-2 could impact how well our bodies can respond to future coronaviruses. Vaccines, if developed properly, provide an opportunity to induce the type of trained immunity that is optimal for mounting protective immune responses, not only against SARS-CoV-2, but also against future infections with coronaviruses and/or their associated vaccines.

Tuberculosis response

Interestingly, some scientists have proposed to harness the concept of trained immunity in a related context. Specifically, there is evidence to suggest that individuals who received a vaccine against tuberculosis may be partially protected against SARS-CoV-2.

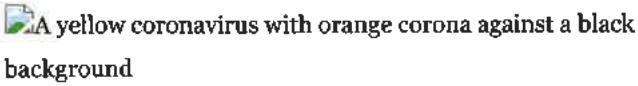
A cluster of pink rod-shaped bacteria on a black background

Scanning electron micrograph of Mycobacterium tuberculosis bacteria. (NIAID), CC BY

Tuberculosis is a respiratory disease caused by a bacterium. In contrast to many bacteria, this one, like viruses, lives inside cells. The vaccine formulation uses a live, but attenuated (modified or weakened) bacterium that is very similar to the one that causes the disease. Since it is a live bacterium, it can infect cells in the same way that the disease-causing bacteria do.

The result is an appropriate immune response that happens to be of the same type that is optimal against viruses. Scientists have concluded, therefore, that the tuberculosis vaccine might be training the immune system in such a way that it can respond ideally to other pathogens that live inside cells, including viruses like SARS-CoV-2.

Evaluating responses



A yellow coronavirus with orange corona against a black background

Colourized transmission electron micrograph of SARS-CoV-2, the virus that causes COVID-19. (NIAID), CC BY

A heavy emphasis is being placed on quantitative aspects of candidate COVID-19 vaccines, such as whether they generate high levels of antibodies. Many health regulatory agencies are poised to approve COVID-19 vaccines that reduce the burden of disease but do not induce immunity to completely prevent infection and transmission. But they should be cautious and ensure that these vaccines do not train our immune system for a response that is not optimal.

By thoroughly evaluating the nature and duration of the immune response induced by a prospective COVID-19 vaccine, we can ensure specific, effective and sustained responses against SARS-CoV-2. Specifically, vaccine developers should be able to answer these questions:

1. Did the vaccine induce an immune response that is optimal against viruses? A balanced antiviral response should include antibodies to prevent the virus from infecting host cells and replicating inside them, and T cells to kill viruses that get past the antibody barrier. Importantly, the antibodies should be of antiviral types.

2. Were there antibody responses in the respiratory tract, and do these antibodies efficiently neutralize the virus? There is significant focus placed on measuring antibody responses in the blood, but SARS-CoV-2 infects mucosal surfaces including the respiratory tract, and it is important to ensure that the vaccine induces antibodies at these relevant locations. Also, it must be noted that appropriate antibody responses against viruses are usually of much lower magnitude than those directed against extracellular bacteria. A large quantity of antibodies may seem promising, but the amount is not nearly as important as the types and locations of these antibodies.

The take-home message is that we should insist on maintaining a very high standard for a COVID-19 vaccine; one that will induce a qualitatively appropriate immune response that will protect us from infection with SARS-CoV-2.

Like an athlete, we need to avoid training our immune system in a way that contradicts the end goal. For long-term health, we must ensure that our immune systems are trained in a way that will allow us to respond most effectively against future highly pathogenic coronaviruses, some of which may prove to be more dangerous than the current one.

Mink can be readily infected with SARS-CoV-2 and then pass the virus to humans. (Shutterstock)

The mink link: How COVID-19 mutations in animals affect human health and vaccine effectiveness

Published: November 22, 2020 9.46am EST

The importance of commercially raised animals in the COVID-19 pandemic has received much attention in the past few weeks, when a new variant of SARS-CoV-2 was detected in farmed mink. Unfortunately, mink tend to be relatively susceptible to respiratory infections, and these can readily spread through mink farms due to high-density housing.

Data from the Netherlands earlier in the pandemic have revealed that mink can be readily infected with SARS-CoV-2 and then pass the virus to humans. In Denmark, 214 people people have been infected by a variant of SARS-CoV-2 that is presumed to have mutated in Danish mink. Over 200 mink farms had tested positive for SARS-CoV-2, and at least five different mink variants of the virus have been detected so far.

These events initiated a mass culling of farmed mink in that country (although this was limited due to legal issues), and cast a spotlight on the disturbing scenario of human-to-mink-to-human transmission of SARS-CoV-2, with potential for the virus to change in mink prior to re-infecting people.

Mink are semi-aquatic mammals that are relatively susceptible to respiratory infections, which can spread through mink farms, like this one in Belarus, due to high-density housing. (AP Photo/Sergei Grits, File)

Specifically, this latest occurrence unveils the possibility that mink can serve as an alternate host to promote mutations of SARS-CoV-2, which can be passed back to humans and other animals, both domestic and wild and potentially placing the wild mustelid (minks, ferrets and related species) population at risk.

Bridging human and animal health

We are researchers in the fields of virology, immunology and pathology. Our research programs bridge human and animal health and study the transmission of viruses, immune responses to viruses, how viruses cause diseases, and developing strategies such as vaccines to prevent infectious diseases. The recent news linking mink to the current pandemic highlights the importance of research at the interface of animal and human health.

Since the start of the COVID-19 pandemic, the world has learned much about virology, as well as the concept of One Health. At the core of One Health is the idea that human and animal health are intertwined in a shared environment, and that we need to broaden our perspectives beyond human health alone.

Indeed, animals have been at the centre of this pandemic from the beginning. Overwhelming evidence suggests that this coronavirus (SARS-CoV-2), which causes COVID-19, originated from bats. There is debate about whether an intermediate animal host might have harboured additional changes to SARS-CoV-2 to produce the current virus that spreads efficiently person to person. The leading candidate for this is a scaly anteater known as a pangolin.

A pangolin emerging from a grassy area.

The pangolin, a scaly anteater, may have been an intermediate host for the SARS-CoV-2 virus. (AP Photo/Themba Hadebe)

What is known for sure is that changes to coronaviruses can occur over time due to inherent and purposeful errors in these viruses' ability to copy their genetic codes. This allows a virus to make small changes over time and is an efficient way for them to adapt to new environments.

Changes in the spike protein

One of the recently identified Danish mink strains is particularly concerning because changes in the genome occurred in what is called the virus's spike protein, which it uses to enter human cells. These changes have been detected in 12 human cases related to this particular mink variant. Fortunately, this change does not seem to correlate with worse clinical outcomes, based on a small number of cases.

The spike protein is also the primary target of natural and vaccine-induced immune responses to the virus. In theory, if SARS-CoV-2 mutates too much, the immunity derived from the parental virus, acquired either by natural infection or vaccination, could become less effective against the new strain.

A model of a spike protein in the foreground with the model of the virus in the background

The good news is that, so far, there's no evidence that the mink-derived SARS-CoV-2 mutant can bypass natural or vaccine-induced immunity. Fortunately, our immune systems are designed to generate antibodies against multiple parts of the spike protein. This means that if only a small part of the spike protein is mutated, antibodies against other parts of the protein should still confer at least some protection.

'Plug-and-play' vaccine technology

The fact that SARS-CoV-2 can change highlights the need for vaccines that not only induce protective antibodies but that can also elicit robust T cell responses, which is the other major mechanism by which our immune systems can kill viruses. Like antibodies, T cells will target multiple parts of viral proteins, thereby increasing the chance of maintaining immunity against non-mutated regions of the proteins.

It might also be important to consider making vaccines that target more than one of the proteins from SARS-CoV-2. It's very difficult for a virus to make major changes to multiple proteins without compromising its fitness.

Read more: Training our immune systems: Why we should insist on a high-quality COVID-19 vaccine

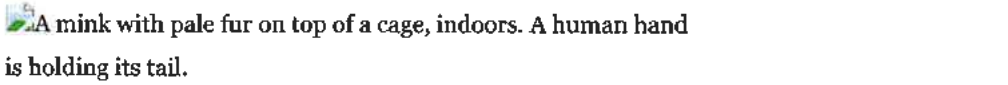
The other issue that the mink SARS-CoV-2 brings to the forefront of the vaccine development effort is the need for vaccines that are "plug-and-play." These are vaccine technologies where the viral protein the vaccine is designed to target can be readily swapped with a different version of the viral protein.

Once approved by health regulators as being safe and efficacious against a highly pathogenic coronavirus, such technologies could, in theory, be rapidly modified to target emerging mutant viruses; akin to the annual flu vaccine that gets modified every year to target emerging influenza virus variants.

Addressing threats and managing health

With mink being confirmed only recently as a possible reservoir for SARS-CoV-2, more research is urgently needed to inform rationally based decisions to cull millions of these animals. Even if mass cullings continue, it is unlikely that mink farms will be completely phased out at the global level in the near future. So the question becomes how do we manage the potential threat to human health of SARS-CoV-2 in mink over the long term?

First, enhanced biosecurity measures should be implemented on mink farms.



A mink with pale fur on top of a cage, indoors. A human hand is holding its tail.

Farmed mink, like this one from an Ontario fur farm, should be screened for coronaviruses. THE CANADIAN PRESS/ Geoff Robins

Second, screening of farmed mink for coronaviruses should be added to the surveillance programs of animal health regulatory agencies, with this information made available to human health regulators.

Third, consideration could be given to tailoring COVID-19 vaccines for animal reservoirs, which would now include farmed mink. These recommendations would not only reduce the potential spread of coronaviruses from mink to humans, it would simultaneously address SARS-CoV-2-related health issues for mink. Indeed, mink can develop COVID-19 after becoming infected with SARS-CoV-2 and it can sometimes be severe and lethal, with no effective current treatment.

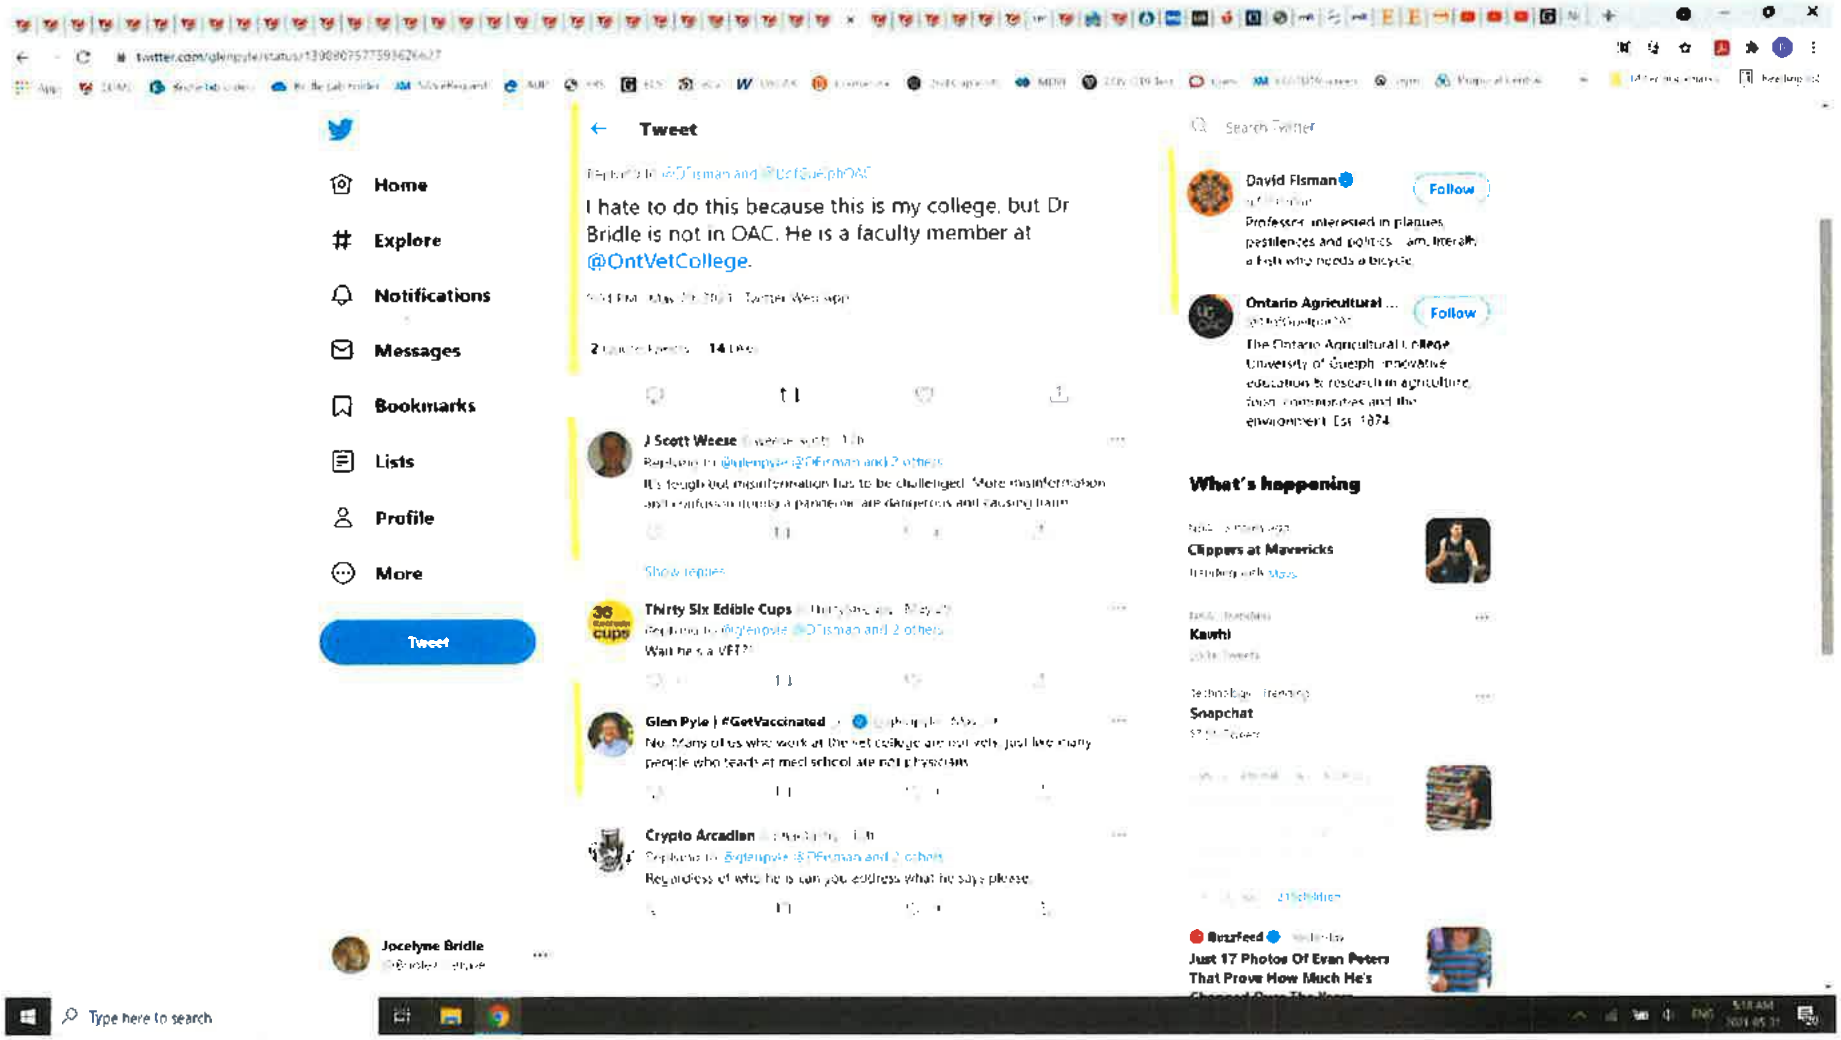
Subject: misinformation

Scott,

I see you have entered the foray...

Court File No./N° du dossier du greffe : CV-22-00691880-0000



...what information are you referring to Scott? And what misinformation did I give? Interestingly, since your communication was in text, you had ample opportunity to describe: (a) what exactly you were rebutting in terms of the science I was interviewed about; and (b) citations to back-up your claim of misinformation. This is akin to saying "my colleague is giving misinformation and I can prove it with my lack of information to back up my claim". I gave a five-minute interview over the radio. You do realize that I can't show papers via the air waves, right? So what information are you criticizing? Did you have any idea what papers I was referring to? FYI, I have attached a brief report to back-up my very legitimate concerns for the health and safety of all Canadian children. I would be happy to debate with you anytime about COVID-19 vaccines if you like to do so. In the report that I have attached, please go to the link to Pfizer's own biodistribution data showing that their vaccine platform travels far and wide throughout the body and accumulates in many tissues. Also, see their report to the European Medicines Agency in which they admit that they have no pharmacokinetic/biodistribution data with the actual vaccine that is going into our children. These are basic studies that should always be done prior to any vaccine being used. Using this vaccine in children without proper biodistribution and additional

Electronically filed / Déposé par voie électronique : 18-Dec-2023
Toronto Superior Court of Justice / Cour supérieure de justice

Court File No./N° du dossier du greffe : CV-22-00691880-0000

safety data that looks at the effect of depositing the vaccine into a plethora of tissues is scientific blasphemy. Do you really think, on this basis, that there are no legitimate safety issues that should be addressed? ...because I can tell you from years of experience that is not how one goes about developing a novel treatment with integrity.

Next time, before you go ahead and fuel a fire that is roasting a colleague, please consider talking to me to determine what my rationale is. What you did here was immature and disrespectful. Do you realize the harm this smear campaign is doing to me?

I must say, it's great to have colleagues like you and Glen around. It is creating a great collegial work environment.

Jeff and Shayan: is this behaviour from Glen and Scott going to be condoned? Jeff, you will recall that Scott already implied that I didn't have the right to hold an opposing view in a recent department meeting. In the current situation, it is ridiculous that I have to present a report to show my colleagues that I actually know what I'm talking about just so I can get them to leave me alone in the world of social media. I think that this harassment in the workplace needs to stop.

Sincerely,
Byram

Hi Paul, Andrew, Cathy, Lucy and David, I hope you are keeping well this summer and enjoying the outdoors. I received this letter against Dr Bridle regarding his views about vaccine safety today, and I was surprised to see your names on the list of faculty in support. I have great respect for you all and thought you would advocate open discussion about such an important generational issue.

Byram is an expert in his field, and I share many of his concerns regarding vaccinating children, and also pregnant women.

The spike protein, regardless of whether or not it is from SARS-CoV2 or a vaccine, is bioactive. The mRNA vaccines use lipid nanoparticles that accumulate in numerous tissues throughout the body, which means spike protein can potentially be synthesized throughout the body. In mice, the S1 protein has also been shown to cross the BBB. As you well know, the spike protein can bind to ACE2 receptors; however, it also appears to bind to endothelial cell integrins, alpha7 nicotinic acetylcholine receptors, and Toll-like receptor 4 that results in activation of nuclear factor- kappa B leading to inflammation. There is also evidence that the spike protein can act as a superantigen eliciting polyclonal T cell activation. Also, the spike protein shares similarities to numerous host proteins setting the stage for a potential autoimmune response in at-risk people.

As this pandemic has unfolded, we have come to see that AVRs do occur as a result of COVID19 vaccination, which now include anaphylaxis, blood clots, myo and pericarditis, Guillian Barre-like Syndrome and other neurological outcomes. We were told, "the vaccines are safe and that the best vaccine is the first vaccine offered to you"; you must agree by now that this statement is not true.

It is surprising to me that someone like Byram, who is expressing concerns about vaccine safety, is shut down after providing evidence of their potential risk, when it is supposed to be the vaccine makers who should be providing the evidence of their safety!

The Canadian government is clearly making up its own vaccine plan by mixing vaccines, extending their shelf-life, wanting to vaccinate people who have already had COVID19, and vaccinating children 12+ years of age. They are also looking at vaccinating children 6-12 years of age with the same concentration of vaccine!

I, for one, advocate that everyone who wishes to receive a vaccine, be antibody tested before they get poked. There is no scientific evidence or immunological rationale for vaccinating people who have already had COVID. These vaccines could be better used on "naive" people, and this would potentially alleviate risk to people with previous immunity, which appears to be long-lasting. The safety of these vaccines has not been thoroughly tested in pregnant women and no one is talking about risk of exposure in utero, especially in the 3rd trimester when miscarriages are less likely to occur. As for children, they should also be antibody tested. I am willing to bet that many of them already have protective natural or cross-reactive immunity. For those that do not, then vaccination could be considered, but not with this generation of vaccines unless their safety is confirmed.

By the way, I have had my serum antibody assessed, and I exhibit a profile of someone who has already had COVID19! I don't recall feeling sick this past year. Perhaps, I was inoculated while volunteering on campus for the rapid antigen test. Perhaps, the face masks don't work to stop an airborne virus!

I am not writing to influence your view, I am only asking that you let others advocate for those who can not speak. This is our academic responsibility! I suspect that public confidence in vaccines will be greatly affected by all the government blunders that have occurred during the past 15 months; which is a shame because We all know how important vaccines are for preventing endemic and emerging diseases.

Best regards, N

March 3, 2021

Dear Professor Charlotte Yates, President and Vice-Chancellor, and **Professor Gwen Chapman**, Interim Provost and Vice-President (Academic):

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought (*i.e.* acquisition of immunity). In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have been commissioned by the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area. Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses. Among the many reasons for this is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to allow SARS-CoV-2 to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada. It has become clear that we can't continue to rely on continual lockdowns. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. **It is from this perspective that we would like to recommend the following core strategies to support re-opening the University of Guelph campus to in-person learning in the Fall 2021 semester:**

1. **Offer comprehensive and sensitive testing for evidence of seroconversion (antibodies) against SARS-CoV-2.** Ever-accumulating data demonstrate that both naturally acquired, and vaccine-induced immunity can provide at least some level of protection from reinfection from the parental and current variant forms of SARS-CoV-2. Evidence of protective immunity either prior to and/or after vaccination would provide valuable information to guide decisions. This testing should be offered to members of the university that are both on- and off-campus. Several options for antibody testing are currently available in Canada. For example, LifeLabs currently has a test available. Even better, we have a colleague at the University of British Columbia who has developed the most comprehensive and sensitive test for seroconversion that we are currently aware of. Through collaboration with this colleague, we would be happy to assist with getting a local lab (possibly our own Animal Health Laboratory, which has an excellent quality control program and experience getting novel tests up and running) set-up to run this cutting-edge test.
2. **Offer strategically prioritized vaccinations.** Vaccination against SARS-CoV-2 should be offered to individuals wanting to return to campus. Prioritization should be based on risk of an infection progressing to disease (*i.e.* COVID-19). If doses are limited, vaccines would best be used in individuals with no evidence of immunity (based on testing in highlighted in point #1). Importantly,

vaccines should be administered precisely according the protocol that was used to have them approved for emergency use until further data is available on alternative protocols. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented evidence of it being relatively ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf). Vaccinations should be offered to university community members that are both on- and off-campus.

3. **Offer rapid antigen screening tests to detect the presence of SARS-CoV-2.** This is currently being tested on campus, and if successful, it would be logical to implement this approach more widely. It is very convenient for the workplace and should be offered to university community members that are both on- and off-campus.
4. **Offer off-campus learning/working accommodations for high-risk individuals.**
5. **Consider implementing supplemental testing.** Additional tests could help manage COVID-19 on-campus. For example, testing wastewater from buildings on campus, with an emphasis on residences could help identify 'hot spots'.
6. **Consider incorporating comprehensive data collection in consultation with our Research Ethics Board.** A lack of concerted efforts to collect comprehensive data sets has slowed the progress of research in many jurisdictions in Canada. The University of Guelph could provide a detailed analysis to support a return to campus at other institutions. Our Department of Population Medicine would be well-equipped to oversee this type of data collection. However, the rollout of vaccines and tests should not be delayed for establishing such a data collection infrastructure; rather, the infrastructure for research-quality data collection could interface with the rollout when it is ready.

Note: Implementation of suggestions 1-5 could have an impact on public health directives. Specifically, it would facilitate discussions around reduced physical distancing. Reducing physical distancing from two meters to one meter in classrooms could have a major positive impact on returning to in-person learning.

We would be happy to offer advice as our campus community moves forward. Specifically, Dr. Bridle is willing to serve on any relevant advisory committees and/or he can be a point of contact for our group, with whom he consults regularly. We also have many colleagues in the fields of virology, immunology, and public health at a variety of institutions that we consult with. We look forward to hearing your thoughts about the University of Guelph showing leadership among the academic community in getting students back to in-class learning.

Sincerely,

Dr. Byram W. Bridle

March 5, 2021

Dear Dr. Nicola Mercer, Medical Officer of Health and CEO of Wellington-Dufferin-Guelph Public Health:

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought (*i.e.* acquisition of immunity). In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have been commissioned by the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive and in-depth expertise in this area. Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses. Among the many reasons for this is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to allow SARS-CoV-2 to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada. It has become clear that we can't continue to rely on continual lockdowns. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. **It is from this perspective that we would like to recommend the following core strategies to support re-opening the City of Guelph and the surrounding regions by this Fall:**

1. **Offer comprehensive and sensitive testing for evidence of seroconversion (antibodies) against SARS-CoV-2.** Ever-accumulating data demonstrate that both naturally acquired, and vaccine-induced immunity can provide at least some level of protection from reinfection from the parental and current variant forms of SARS-CoV-2. Evidence of protective immunity either prior to and/or after vaccination would provide valuable information to guide decisions. Several options for antibody testing are currently available in Canada. For example, LifeLabs currently has a test available. Even better, we have a colleague at the University of British Columbia who has developed the most comprehensive and sensitive test for seroconversion that we are currently aware of. Through collaboration with this colleague, we would be happy to assist with getting a local lab (possibly our own Animal Health Laboratory, which has an excellent quality control program and experience getting novel tests up and running) set-up to run this cutting-edge test.
2. **Offer strategically prioritized vaccinations.** Prioritization should be based on risk of an infection progressing to disease (*i.e.* COVID-19). If doses are limited, vaccines would best be used in individuals with no evidence of immunity (based on testing highlighted in point #1). Importantly, vaccines should be administered precisely according to the protocol that was used to have them approved for emergency use until further data is available on alternative protocols. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented

evidence of it being relatively ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf).

3. **Offer rapid antigen screening tests to detect the presence of SARS-CoV-2.** This is currently being tested on the University of Guelph campus, and if successful, it would be logical to implement this approach more widely. It is very convenient for the workplace.
4. **Offer accommodations for remote working/learning for high-risk individuals.**
5. **Consider implementing supplemental testing.** Additional tests could help manage COVID-19. For example, testing wastewater from buildings, with an emphasis on high-density housing and workplaces could help identify 'hot spots'.
6. **Consider incorporating comprehensive data collection in consultation.** A lack of concerted efforts to collect comprehensive data sets has slowed the progress of research in many jurisdictions in Canada. The Wellington-Dufferin-Guelph Public Health in conjunction with the University of Guelph could provide a detailed analysis to support return-to-work and return-to-school policies at other institutions. Our Department of Population Medicine would be well-equipped to oversee this type of data collection. However, the rollout of vaccines and tests should not be delayed for establishing such a data collection infrastructure; rather, the infrastructure for research-quality data collection could interface with the rollout when it is ready.

Note: Implementation of suggestions 1-5 could have an impact on public health directives. Specifically, it would facilitate discussions around reduced physical distancing. Reducing physical distancing from two meters to one meter in workplaces and classrooms could have a major positive impact on returning to in-person work and learning.

We would be happy to offer advice as our regional community moves forward. Specifically, Dr. Bridle is willing to serve on any relevant advisory committees and/or he can be a point of contact for our group, with whom he consults regularly. We also have many colleagues in the fields of virology, immunology, and public health at a variety of institutions that we consult with. We look forward to hearing your thoughts about the Wellington-Dufferin-Guelph Public Health Unite showing leadership within Canada in getting local citizens back to in-person work and in-class learning.

Sincerely,

Dr. Byram W. Bridle

Dr. Sarah K. Wootton
Associate Professor of Virology

Dr. Bonnie Mallard
Professor of Immunology

Dr. Niel Karrow
Professor of Immunology

Dear Fellow Canadians:

We are four faculty members at the University of Guelph. Dr. Byram Bridle is a viral immunologist, Dr. Sarah Wootton is a virologist, and Drs. Mallard and Karrow are immunologists. Generally, policies for COVID-19 have been generated after consultations focusing mainly on the opinions of physicians, epidemiologists, and other public health experts. However, at its core, COVID-19 is a problem at the interface of immunology and virology, both in terms of its pathogenesis and the primary solution being sought, which is acquisition of immunity against the virus SARS-CoV-2. In addition to our group having in-depth knowledge of these fields, Drs. Bridle and Wootton have received funding from the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area.

Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks; this was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed. Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses.

Among the many reasons for this virus becoming endemic is the propensity of SARS-CoV-2 to mutate over time, which will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly-focused immunity that targets a single protein known as the spike. These two major issues will combine to potentiate SARS-CoV-2 being able to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada.

It has become clear that we can't continue to rely on continual lockdowns due to the impact on mental health, delays to other medical treatments, a sinking economy, and so on. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities. It is also important to remember that the majority of cases of COVID-19 in Canada are mild-to-moderate, and the death rate has been quite low (22,514 deaths out of 914,697 cases or 592/million as of March 16 2021 - Coronavirus Dashboard [ncov2019.live]). Sadly, at least 70% of those deaths have been in people over 80 years of age, in long-term care (Dr. R. Bibby, Sociologist, University of Lethbridge; http://www.reginaldbibby.com/specialcovid19analyses.html). On the upside, there is now also good evidence that the majority of those recovered from COVID-19 have protective immunity (reviewed by Sette and Crotty, Adaptive immunity to SARS-CoV-2 and COVID-19, Cell (2021), DOI: https://doi.org/10.1016/j.cell.2021.01.007).

It is from this perspective that we have been advocating for several core strategies to support re-opening our country to in-person work and learning. An important aspect of this is offering strategically prioritized vaccinations. Specifically, we have been advocating for the **administration of safe and effective COVID-19 vaccines according the protocol that was used to have them approved** for emergency use, until further data is available and reviewed and approved by Health Canada to support alternative protocols. In support of this goal, we have two recommendations:

1. Consideration should be given to avoiding the use of the AstraZeneca vaccine, for which there is documented evidence of it being ineffective against the South African variant of SARS-CoV-2, which we reiterate is now in Canada. Specifically, it was shown to be only 10% effective against the South African variant, with the cut-off for approval being 50%. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf). Additionally, its use has been suspended in at least ten European countries until undesirable potential side-effects can be further investigated. For Ontarians, the Chief Medical Officer definitively stated in a letter to pubic health units in the province that individuals may opt out of receiving the AstraZeneca vaccine on the basis that it is admittedly of lower efficacy than the others (see the highlighted text on page 2 of the attached letter).

2. The intervals for the two-dose COVID-19 vaccines should adhere to what was officially approved by Health Canada and the manufacturers, which is 21- and 28-days for the Pfizer and Moderna vaccines, respectively. The rationale for this is presented below...

The history of Canada's move to extend COVID-19 intervals to an unprecedented four months.

Last week, the CBC launched a story to highlight the path that has led many jurisdictions in Canada to begin implementing an interval of up to four months for both the Pfizer and Moderna COVID-19 vaccines (https://www.cbc.ca/news/health/canada-covid-19-vaccine-delay-risk-1.5939134). It apparently began with a letter from an epidemiologist at the British Columbian Centre for Disease Control to the editor of *The New England Journal of Medicine* (https://www.nejm.org/doi/full/10.1056/NEJMc2036242). In this letter it was claimed that Pfizer failed to realize the efficacy of its own vaccine and that its effectiveness as a single-dose regimen is actually a remarkable 92%. It is important to note that this is based on an extrapolation of a statistically underpowered, biased, limited data set from a trial that was never designed to test single-dose efficacy. Further, the extrapolation required several assumptions to be made that may or may not be true; there simply is no empirical data to know either way.

What many do not realize is that the researchers for Pfizer published a rebuttal to this letter in which they stated: "**In response to Skowronski and De Serres: we would like to emphasize that alternative dosing regimens of BNT162b2 have not been evaluated.**" Pfizer's own data has suggested that single-dose effectiveness might be just over 50%, with their admission of the caveat that their study was never designed to test this properly. Nonetheless, the idea that extended intervals will work well is being propagated, despite a lack of empirical evidence. Indeed, Dr. Bridle has confirmed via interviews with people coming out of local vaccine clinics that some of them are being told that a single dose has been shown to be 92% effective based on 'published data'. This is simply untrue and not the way science is supposed to work. The validity of alternative protocols is up for debate in the scientific community.

Any intervals that deviate from what Health Canada and the vaccine manufacturers have agreed to, represents experimentation, especially in the absence of any new validated data from a phase 3 clinical trial. However, in Ontario and many other jurisdictions in Canada, the change in the vaccine interval has been proposed. See the attached letter from Ontario's Chief Medical Officer as an example of this. In short, the intervals have been lengthened without sufficient empirical data to justify it. In contrast, the intervals provided by Health Canada are based on empirical data. The effectiveness of the two-dose regimens with 3- or 4-week intervals is known. The effectiveness of the two-dose regimens with any other interval is a 'best guess'. This background leads into a potentially more serious issue regarding informed consent...

Is informed consent being practiced properly in COVID-19 vaccine clinics?

In Ontario, the attached consent form should be hard-signed by everybody prior to receiving one of the experimental vaccines. Please note that this form requires a person to have read or to have read to them the vaccine information sheet (see the highlighted text on page 3 of the consent form). Please note the highlighted text on pages 4 and 6 of the vaccine information sheet that is appended to this letter. Consent is being given to receiving the dose at Health Canada's recommended interval of 3- (Pfizer) or 4-weeks (Moderna). No alternative intervals are described. Remarkably, however, many (if not most) attendees at the COVID-19 vaccine clinics are being told after receiving their first dose (*i.e.* once they are committed to the treatment) that they will likely have to wait up to four months to receive the second dose. **People are consenting to the 3-4-week interval** (3 weeks for Pfizer's vaccine; four weeks for the Moderna vaccine) **but are then being told that they cannot receive the second dose for another four months.** For those who would like to insist on receiving their vaccine as per Health Canada's recommended interval, we suggest you take a hard-copy of the vaccine information sheet to the clinic and have

dose.

Why might the interval for two-dose vaccines matter?

Some proponents of lengthening the interval argue there can be no harm. However, there is some scientific basis for suggesting that lengthening intervals could cause harm: 1. The companies themselves suggest a single dose is significantly less efficacious than two doses. This could put individuals at prolonged risk of getting infected while waiting for the second dose. This could be a particular problem for those who are at high risk. 2. It is unknown if the duration of immunity (i.e. how long a person is protected) conferred by a single dose extends to four months; it is possible that there may be no protection at this point. 3. It is unknown if immunological memory conferred by the first vaccine will last long enough for a second dose, given four months later, to serve as a proper 'booster vaccine'. If a proper boost is not conferred, the two-dose effectiveness could be reduced below the 95% effectiveness shown with the approved interval. 4. Induction of long-term, relatively weak immunity could potentially promote the emergence of immune-evasive mutants. This would be similar to what has been observed over and over again with the emergence of dangerous antibiotic-resistant bacteria; it is potentiated by the misuse of the therapeutic agents designed to effectively treat the pathogens. Promotion of immune-evasive SARS-CoV-2 would put everyone at greater risk. Although these are cautionary possibilities, **they are no less valid than the speculations that led to adopting untested long intervals**. Given these are novel nucleic acid vaccine platforms, approved for emergency use only, it might be wise to err on the side of caution. The take-home message is: Longer intervals might be OK, but they also might create problems. We simply don't know yet. On this basis, **those who want to receive the vaccines according to how they were approved for emergency use should be entitled to this.** However, **public health officials seem to be over-riding this right, even though it contradicts their own informed consent procedure, Health Canada, and the vaccine manufacturers.**

With sincere concern for our fellow Canadians,

Dr. Byram W. Bridle

Dr. Niel Karrow
Professor of Immunology

March 23, 2021

Dear Fellow Canadians:

Scientists Express Urgent Concerns Over Current COVID-19 Vaccine Policies

University Of Guelph Faculty Speak Up:

The following urgent concerns are being expressed by the following faculty members at the University of Guelph:

- Dr. Byram Bridle is a viral immunologist
- Dr. Bonnie Mallard is an immunologist
- Dr. Neil Karrow is an immunologist

Generally, policies for COVID-19 have been generated with relatively little consultation with immunologists, including viral immunologists. However, at its core, COVID-19 is a problem at the interface of immunology and virology.

This interface is both in terms of its pathogenesis and the primary solution being sought, which is acquisition of immunity against the virus SARS-CoV-2. In addition to our group having in-depth knowledge of these fields, Dr. Bridle received funding from the federal government and the government of Ontario to develop vaccines for COVID-19. As such, our group has extensive expertise in this area. Please note that information about COVID-19 vaccines is rapidly changing. The information presented below is accurate as of March 23, 2021.

Has The Goal To Flatten The Curve Been Forgotten?

Early in the pandemic, the goal was to 'flatten the curve' of documented cases of COVID-19 by implementing a lockdown for a few weeks. The purpose was to facilitate hospitals being able to support us in learning how to live with SARS-CoV-2 without medical resources becoming overwhelmed.

Although never clearly stated, the goal seems to have morphed into a 'zero tolerance policy' in which life will not return to normal until daily cases have been eliminated. The large amount of available scientific data suggests this will not be a feasible goal. Indeed, COVID-19 will almost certainly become endemic, akin to the annual outbreaks of influenza viruses.

Will SARS-CoV-2 Become Endemic?

Among the many reasons for this virus becoming endemic is the propensity of SARS-CoV-2 to mutate over time. This will result in the ongoing emergence of novel variants, and this problem is exacerbated by the fact that current vaccines against SARS-CoV-2 confer overly focused immunity that targets a single protein known as the spike.

These two major issues will combine to potentiate SARS-CoV-2 being able to escape vaccine-induced immunity. Indeed, this has already happened as demonstrated by the AstraZeneca vaccine failing in a clinical trial in South Africa against the South African variant, which is already circulating in Canada.

How Can We Live With This Virus While Still Maximizing Health And Safety?

It has become clear that we can't continue to rely on continual lockdowns due to impact on mental health, delays to other medical treatments, a sinking economy and so on. Instead, we must return to the original goal of learning to live with this virus while maximizing the health and safety of our communities.

It is also important to remember that the majority of cases of COVID-19 in Canada are mild-moderate, and the death rate has been quite low (22,676 deaths out of 933,798 cases or 596/million people as of March 22, 2021 - Coronavirus Dashboard (ncov2019.live).

Sadly, at least 70% of those deaths have been in people over 80 years of age, in long-term care (Dr. R. Bibby, Sociologist, at the University of Lethbridge – Research of Reginald W. Bibby (reginaldbibby.com)).

On the upside, there is now also good evidence that the majority of those recovered from COVID-19 have protective immunity (reviewed by Sette and Crotty, Adaptive immunity to SARS-CoV-2 and COVID-19, Cell (2021), https://doi.org/10.1016/ j.cell.2021.01.007).

Therefore, we need to identify those with immunity from natural exposure using available antibody testing, and strategically prioritize those at highest risk, who need and want to be vaccinated, according to the manufacturers currently approved vaccination protocols.

How Can Vaccines Be Prioritized According To Manufacturers Approved Protocols?

It is from this perspective that we have been advocating for several core strategies to support re-opening our country to in-person work and learning. An important aspect of this is offering strategically prioritized vaccinations.

Specifically, we have been advocating for the administration of safe and effective COVID-19 vaccines according the protocol that was used to have them approved for emergency use, until further data is available and reviewed and approved by Health Canada to support alternative protocols.

In support of this goal, we have two recommendations:

1. Consideration should be given to avoiding the AstraZeneca vaccine, for which there is documented evidence of it being ineffective against the South African variant of SARS-CoV-2, which is now in Canada. It was only 10% effective against the South African variant, with the cut-off for approval being 50% (https://www.nejm.org/doi/full/10.1056/NEJMoa2102214?query=featured_home).

2. It has also proven to be less effective in a head-to-head comparison with Pfizer's vaccine (https://www.cell.com/cell/pdf/S0092-8674(21)00226-9.pdf).

   For Ontarians, the Chief Medical Officer definitively stated in a letter to pubic health units in the province that individuals may opt out of receiving the AstraZeneca vaccine on the basis that it is admittedly of lower efficacy than the others (see the highlighted text on page 2 of the attached letter).

3. The intervals for the two-dose COVID-19 mRNA vaccines should adhere to what was officially approved by Health Canada and the manufacturers, which is 21- and 28-days for the Pfizer and Moderna vaccines, respectively. The rationale for this is presented below...

Why The Concern Over Changing The Manufacturers Approved Protocols?

The history of Canada's move to extend COVID-19 intervals to four months is unprecedented. Recently, the CBC launched a story to highlight the path that has led many jurisdictions in Canada to begin implementing an interval of up to four months for both the Pfizer and Moderna COVID-19 vaccines (https://www.cbc.ca/news/health/canada-covid-19-vaccine-delay-risk-1.5939134).

It apparently began with a letter from an epidemiologist at the British Columbian Centre for Disease Control to the editor of *The New England Journal of Medicine* (https://www.nejm.org/doi/full/10.1056/NEJMc2036242).

In this letter it was claimed that Pfizer failed to realize the efficacy of its own vaccine and that its effectiveness as a single-dose regimen is a remarkable 92%. It is important to note that this is based on an extrapolation of a statistically underpowered, biased, limited data set from a trial that was never designed to test single-dose efficacy. Further, the extrapolation required several assumptions to be made that may or may not be true; there simply is no empirical data to know either way.

What many do not realize is that the researchers for Pfizer published a rebuttal to this letter in which they stated: "In response to Skowronski and De Serres: **we would like to emphasize that alternative dosing regimens of BNT162b2 have not been evaluated.**" Pfizer's own data has suggested that single-dose effectiveness might be just over 50%, with their admission of the caveat that their study was never designed to test this properly.

Nonetheless, the idea that extended intervals will work well is being propagated, despite a lack of empirical evidence. Indeed, Dr. Bridle has confirmed via interviews with people coming out of local vaccine clinics that some of them are being told that a single dose has been shown to be 92% effective based on 'published data'. This is simply untrue and not the way science is supposed to work. The validity of alternative protocols is up for debate in the scientific community.

Notably, on March 22nd, Canada's chief science adviser, Dr. Mona Nemer, spoke out against lengthening dosing intervals for Canadian seniors, citing not only a lack of scientific evidence to support it, but even emerging evidence to contraindicate it (https://www.ctvnews.ca/health/coronavirus/research-doesn-t-back-vaccine-dose-delay-for-seniors-canada-s-chief-science-adviser-says-1.5358075).

Any intervals that deviate from what Health Canada and the vaccine manufacturers have agreed to, represents experimentation, especially in the absence of any new validated data from a phase 3 clinical trial. However, in Ontario and many other jurisdictions in Canada, the change in the vaccine interval has been implemented.

See the attached letter from Ontario's Chief Medical Officer as an example of this. In short, the intervals have been lengthened without sufficient empirical data to justify it. In contrast, the intervals provided by Health Canada are based on empirical data. The effectiveness of the two-dose regimens with three-

or four-week intervals is known. The effectiveness of the two-dose regimens with any other interval is a 'best guess'. This background leads into another potentially serious issue regarding informed consent...

Is Informed Consent Being Practiced Properly In Canadian COVID-19 Clinics?

According to Ontario's Ministry of Health website, the attached consent form should be hand-signed by everybody prior to receiving one of the experimental vaccines. Please note that this form requires a person to have read or to have read to them the vaccine information sheet (see the highlighted text on page 3 of the consent form). Please note the highlighted text on pages 4 and 6 of the vaccine information sheet that is appended to this letter.

The Ontario Ministry of Health website appears to be requiring consent to be given to receiving the second dose of the mRNA vaccines at Health Canada's recommended interval of three- (Pfizer) or four-weeks (Moderna). No alternative intervals are described. Remarkably, however, most attendees at the COVID-19 vaccination clinics are being told that they cannot receive the second dose for another four months.

For those who would like to insist on receiving their vaccine as per Health Canada's recommended interval, we suggest you take a hard-copy of the vaccine information sheet to the clinic and have them confirm that they will adhere to the protocol you are consenting to prior to letting them administer the first dose.

WHY MIGHT THE INTERVAL FOR TWO-DOSE VACCINES MATTER?

Some proponents of lengthening the interval argue there can be no harm. However, there is some scientific basis for suggesting that lengthening intervals could cause harm:

1. The companies themselves suggest a single dose is significantly less efficacious than two doses. This could put individuals at prolonged risk of getting infected while waiting for the second dose. This could be a particular problem for those who are at high risk.

2. It is unknown if the duration of immunity (*i.e.* how long a person is protected) conferred by a single dose extends to four months; it is possible that there may be no protection at, or even before this point.

3. It is unknown if immunological memory conferred by the first vaccine will last long enough for a second dose, given four months later, to serve as a proper 'booster vaccine'. If a proper boost is not conferred, the two-dose effectiveness could be reduced below the 95% effectiveness shown with the approved interval.

4. Induction of long-term, relatively weak immunity could potentially promote the emergence of immune-evasive mutants. This would be similar to what has been observed over and over again with the emergence of dangerous antibiotic-resistant bacteria; it is potentiated by the misuse of the therapeutic agents designed to effectively treat the pathogens.

Promotion of immune-evasive SARS-CoV-2 would put everyone at greater risk. Although these are cautionary possibilities, they are no less valid than the speculations that led to adopting untested long

intervals. Given these are novel nucleic acid vaccine platforms, approved for emergency use only, it might be wise to err on the side of caution.

5. A pre-print of a relevant scientific article was posted on-line (https://www.medrxiv.org/content/10.1101/2021.03.03.21251066v1). It has not yet undergone peer review. However, we routinely review these kinds of articles and have concluded that the core data set appears to be valid. This article describes results of a study with the Pfizer vaccine. Importantly, the authors have concluded "since the majority of vaccinees did not obtain neutralizing antibody titers after the first vaccination, we suggest that **postponing a second vaccination with this vaccine is neither advisable for younger nor elderly populations**." In short, a single dose of Pfizer's vaccine would be expected to leave most people unprotected against SARS-CoV-2. Therefore, extending the interval to four months would not meet the goal of getting twice as many people partially protected, as our public health officials are claiming. Instead, it could cause large numbers of people to be left unprotected for a prolonged period.

What's the Take-Home Message?

A longer interval might be okay for the Moderna vaccine, but it also might create problems. We simply don't know yet. Cutting-edge data from a properly conducted scientific study suggested that a prolonged interval for the Pfizer vaccine is dangerous. On this basis, those who want to receive the vaccines according to how they were approved for emergency use should be entitled to this.

However, public health officials seem to be over-riding this right, even though it appears to contradict Health Canada, the vaccine manufacturers, Canada's chief science advisor, and the informed consent procedure posted on the Ontario Ministry of Health website.

With sincere concern for our fellow Canadians,

Subject: Invitation to publicly discuss COVID-19 vaccines for children

Hi Scott and Glen,

I am sick and tired of your immature behaviours in social media. The continual fanning of the flames of the smear campaign against me is hurtful, harmful, and childish. Graduate students of other faculty members have taken notice and are appalled by the ongoing behaviour. Glen, you were caught in an outright lie (see below). You know who set-up the libelous website and lied to our college administration about knowing this. Will you reveal the name of the person who set-up the site to facilitate its removal or do you continue to feel it is appropriate to cause major ongoing harm to the career of a colleague? It is notable that neither one of you has been willing to engage me in any discussions about the science. Talking to someone who can respond in real-time is very different than slamming them in one-sided Tweets. I do not have a social media presence and you provide great examples of why this was a wise decision. It is time to start acting your age. I invite you to discuss the science underpinning the use of COVID-19 vaccines in children in an on-line public forum. You are the local experts on COVID-19 vaccines and now have an opportunity to demonstrate to our colleagues, and the public at large that I do not know what I am talking about in a respectful discussion. We can find a moderator and we can either do this one-on-one, the two of you and then I will choose one colleague to attend with me, or you can even select one additional colleague and we will have teams of three. You have one week to respond to this invitation. The public discussion will take place within a week of me receiving a response. A negative response or non-response will be taken as a public acknowledgement that you have been wrong and will be implied as a public apology. To help you prepare, please see the attached open letter that was written by the inventor of the mRNA vaccine technology, read my guide for parents (the full version, not the two-pager), which can be found at this website: https://www.canadiancovidcarealliance.org/, and view this video in which I rebut every argument made against me that I was aware of... https://rumble.com/vilrsj-doctor-talks-10-dr-byram-bridle-returns-fire-to-critics.html

The time starts now.

A few examples of the many Tweets sent to me by horrified graduate students and some colleagues from around the world can be found below (Scott and Glen, do you really want the public and our trainees to believe that this is how we conduct our business at the U of G?; Are you willing to work towards re-building a respectful work environment at OVC?)...

Sincerely,
Byram

RE: smear campaign

Glen Pyle <gpyle@uoguelph.ca>
Sun 3/30/2021 1:00 PM
To: Byram Bridle <bbridle@uoguelph.ca>
Cc: Jeffrey Wichtel <jwichtel@uoguelph.ca>; Shayan Sharif <shayan@uoguelph.ca>; Brandon Lilke <blilke@uoguelph.ca>

Hi Byram.

I'm removing some of the cc on this in the hope that a more focused discussion will help. Jeff conveyed to me the suggestion that we try a more focused approach and I understand he did the same for you. Hopefully this helps.

Here is the lie!

First, I appreciate the clarification about the article. Stress or not, I can see how a small language error (inadvertent) can cause a misunderstanding. Happy to move past that.

Second, I don't know who made the website. You've mentioned you are not on social media so you may not be aware that some people chose to remain anonymous. The website was flagged to me and that was the info I was given. Others tried to tag it to Dr Fisman and someone mentioned a hacker. I simply clarified that my understanding was this was not the case. I think you can appreciate that had someone been mistakenly linked to material they didn't create, that could create stress for them.

Finally, I would like to point out that anything I posted was based on publically available information and that I have stuck to the evidence. I have not attacked you as a person and have no intention of doing so. I think we can have profound disagreements about the science and stay away from character attacks. If others have made it personal I don't condone that. In all honesty, I have not seen personal attacks like that, but these things do happen on social media and I don't think they help any side of the debate. I myself have been on the receiving end, including threats of violence, so I can speak from experience.

We have deep disagreements over the science. I have no issue with you presenting your arguments based on studies and data, and have never called for your academic freedom to be curtailed. You don't need my permission, so hopefully that last statement doesn't come across like that. I hope that you will afford me the same opportunity to discuss the scientific literature, and we can disagree (or perhaps be swayed by each other's arguments).

I am sorry you feel you have been personally attacked and that this has created stress. If I have inadvertently posted something that appears to be personal, I apologize without reservation. I can't be responsible for the words of others, but let me clearly state that anyone who attacks you as a person is not supported by me.

Glen.

Here is Scott defending the release of my parents' private medical information by a practicing physician (Dr. David Fisman, who seves on Ontario's COVID-19 Science Advisory Table)...

It seems like Bridle (surprise, surprise) misinterpreted a comment and (surprise, surprise) continues to spew misinformation about it.

I've seen nothing supporting it and how would the person he's accusing have access to Bridle's parents' info?

Just more misdirection.

1

Patti @booboobunster · 12h

I see your a collegue of Dr. Bridles. Are you in on the smear? And if so why? Is he not a credible scientist? And if not why are you all just coming forward now?

1 2

J Scott Weese
@weese_scott

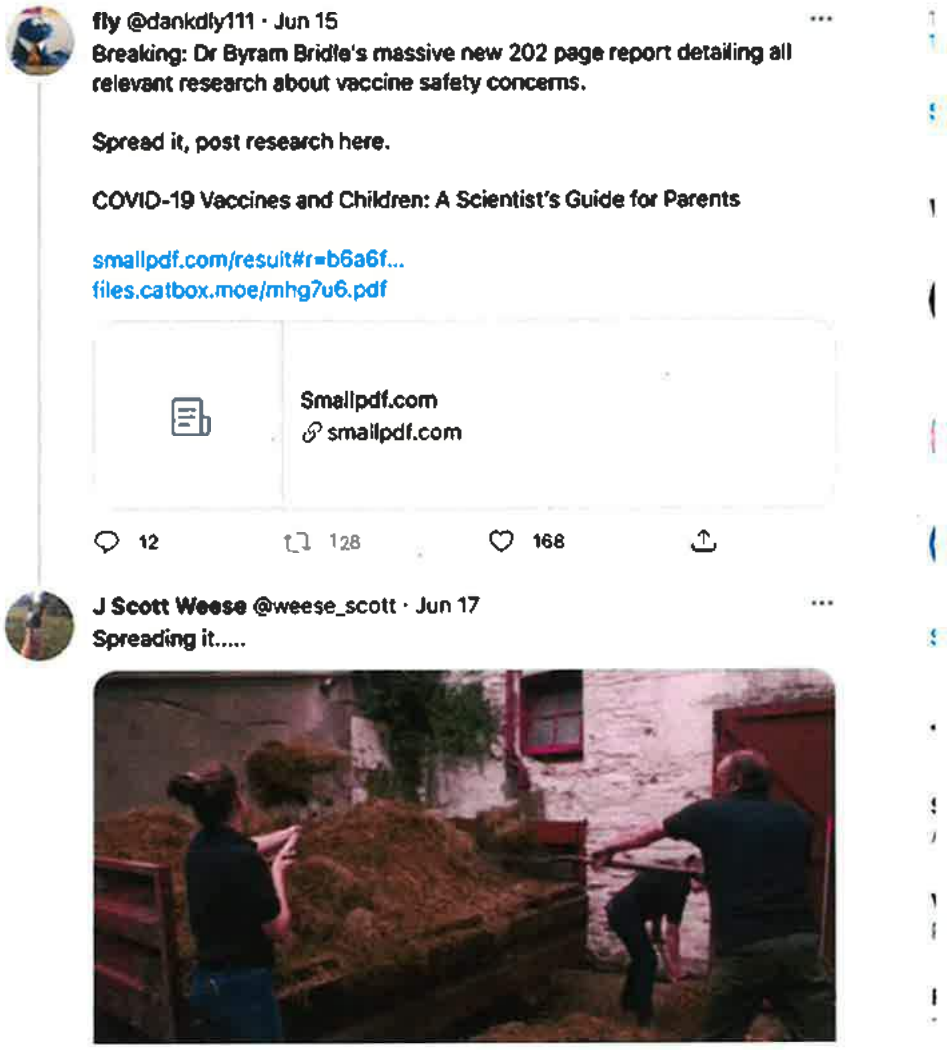
Replying to @booboobunster @diana_c2021 and 3 others

What smear? Many people are simply pointing out all the flaws and misinterpretations.

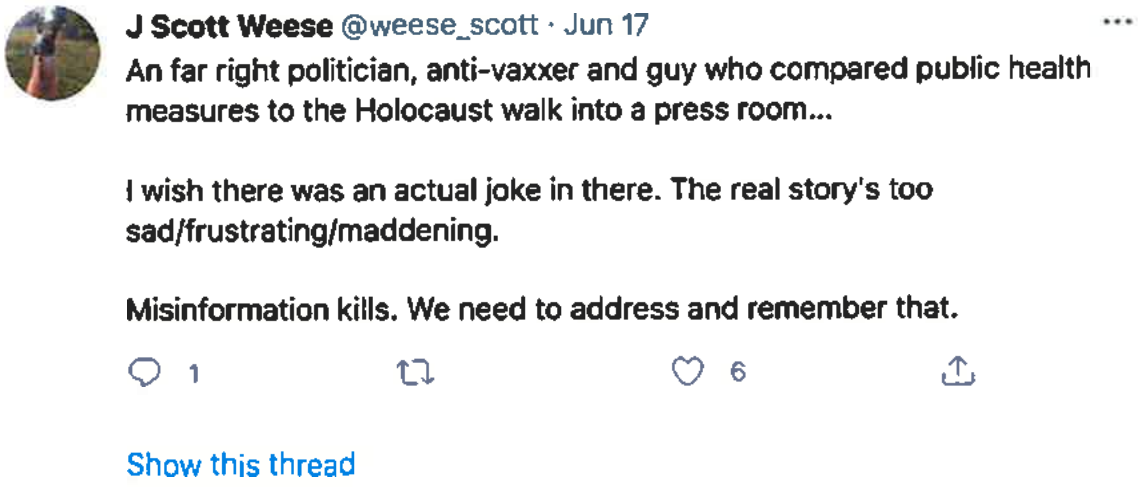
His information is not credible, as has been pointed out by many people and groups, including the authors of the papers he cites as evidence.

9:30 AM · Jun 21, 2021 · Twitter Web App

An example of Scott's mature approach to scientific discourse...



Another sign of Scott's maturity (this was in response to a press conference that I was invited to participate in at Parliament Hill about censoring open scientific and medical discussions)...



...publicly referring to a vaccinologist whose research program and publication record focuses on vaccines is libel.

Subject: Department of Pathobiology

CAUTION: This email originated from outside of the University of Guelph. Do not click links or open attachments unless you recognize the sender and know the content is safe. If in doubt, forward suspicious emails to IThelp@uoguelph.ca

Hi Brandon, I understand that you are now the Chair of Pathobiology. Congratulations, I'm sure you will do an excellent job. I have greatly enjoyed working with members of your department and have much respect for most of your faculty. I have collaborated with You, Caswell, Plattner, Sharif, Mallard, Sargolzaei, Peregrine, and Wootton, and have been blessed with the opportunity to exchange communications with Bienzle, Boerlin, Gyles, Bridle, Hayes, MacInnes, Lumsden, Nagy, Prescott, Hodgins and others while sitting on various university committees.

As I see it, something is seriously wrong over there!

I came across a Tweet that I find very disturbing (attached). I don't know Weese, nor do I care to, but his tweets are very immature and unprofessional. I believe as colleagues, we should be able to listen to and respect each other, and hopefully learn together. We are stronger as a group than we are individually. I am embarrassed by Weese's childish behaviour and I am ashamed to be affiliated with the same university that he attends. Since when did we learn to steep so low? Is it a cry for attention because we have been in isolation for the last 18 months? If he disagrees with Bridle, then why doesn't he just sit down with him and discuss his concerns? Why the public slandering? This kind of caddy behaviour makes us all look bad and it says so much more about Weese's character than what Bridle stands for. Moving forward, I think a mediator should be considered. In the short-term please somehow curtail these Tweets. Thanks N
